PALÆONTOLOGY:

Vol. V. Part I.

LAMELLIBRANCHIATA

I.

TEXT AND PLATES.

CONTAINING DESCRIPTIONS AND FIGURES

OF THE

MONOMYARIA

OF THE

UPPER HELDERBERG, HAMILTON AND CHEMUNG GROUPS.

By JAMES HALL,

STATE GEOLOGIST.

15/5/90

ALBANY, N. Y.:
CHARLES VAN BENTHUYSEN & SONS.
1884.

STATE OF NEW YORK,
ALBANY, February 15, 1884.

Published under the supervision of the Trustees of the State Museum of Natural History, pursuant to chapter 355 of the Laws of 1883.

DEDICATION.

To His Excellency

GROVER CLEVELAND,

Governor of the State of New York:

Sir — I have the honor to present to your Excellency a new volume of the Natural History of the State of New York, forming a continuation of the work on the Paleontology of the State.

This volume, together with another to be published early next year, is devoted to the description and illustration of the fossil bivalve shells known as Lamellibranchiata. The entire work will embrace all the fossils of this class from the higher geological formations of the State. The material has been accumulated from various sources during the period since 1843. Eighty plates for these volumes had already been lithographed in 1873, but the publication was delayed for want of legislative authority for the printing. During the session of 1883 an act was passed by the Legislature, and sanctioned by your Excellency, providing for the completion of the entire work upon the Palæontology of the State. The present volume is the first fruit of that act, and I trust its publication may give you personal satisfaction.

Hoping that this volume may commend itself to the students of science and prove not unworthy of the great series of works comprised in the Natural History of the State of New York,

I have the honor to be,

With great respect,

Your obedient servant,

JAMES HALL,

State Geologist.

Albany, February 15, 1884.

Pages 186 and 238, lines 4 and 7, respectively, for Alleghany read Cattaraugus.

The names Philipsburgh and Rockville, are localities referred to in the earlier Geological Reports, from which many fossils were obtained. The former (Philipsburgh) is now known as Belmont. Rockville was a settlement near the mouth of Rock creek on the Genesee, in the township of Belfast, during the construction of the Genesee Valley Canal. The name does not now appear in the Gazetteer.

PREFACE.

The present volume includes the letter press and plates which constitute a portion of Volume V. Part 1, of the Paleontology of New York. It was originally intended to arrange the whole of this material as a volume of text and a volume of plates: but the exigencies of publication have made it necessary to issue a volume of the work at the present time, and in its present form, leaving the remaining portion to constitute a similar volume which will be published early in the next year.

The entire work will embrace the descriptions and figures of all the recognized forms of Lamellibranchiata from the Upper Helderberg, Hamilton, Portage and Chemung Groups within the limits of the State of New York. This volume includes descriptions and figures of the species under the genera included in the accompanying synopsis, belonging to the families. Pectenidae, Pterinidae, Aviculidae, Ambonychidae, and Mytilidae.

The fossil Lamellibranchiata of the higher groups of the New York geological series are often abundant, of great variety of form and of very interesting character. Our earlier knowledge of these fossils is almost wholly due to Mr. Conrad, who described eleven species in the Annual Report of the Geological Survey in 1838; and during the following years this work was continued, both in the Annual Reports of the Survey and in the Journal and Proceedings of the Academy of Natural Sciences of Philadelphia. The total number of species described by Mr. Conrad from all the groups is about one hundred and ten, and fifty of these have been illustrated in the publications of the Academy. The number of species at present known from the same formations is about 600, of which nearly 500 are from the groups above the Oriskany sandstone.

During and since this period the writer has made extensive collections of these fossils, both with his own hands and through the agency of his assistants, preparatory for their illustration in the Paleontology of New York. After having accumulated considerable collections, and feeling the importance of their proper identification, the writer personally engaged Mr. Conrad to examine the whole and to give his determination of the species which he had described. On three several occasions, previous to 1865, Mr. Conrad visited Albany for the express purpose of making these determinations and identifications, labelling one or more of each of those which he recognized as typical forms of the species. Through these means and by later study and comparison it is believed that nearly all the previously described forms have been satisfactorily determined.

The species described in this volume are illustrated from original drawings made from typical or authenticated specimens. These specimens are chiefly selected from the State Museum collections, which were derived from the State Geological Survey, from subsequent acquisition by purchase, or from field collections especially made for this object.

The work of lithographing the plates of the Lamellibranchiata was begun in 1870, and owing to the author's constant occupation in duties pertaining to the State Museum, the supervision of the drawings and lithography were chiefly intrusted to Mr. R. P. Whitfield, who at that time was acting as draughtsman and museum assistant, and the first thirty plates of this volume were drawn, and lithographed, and arranged under his direction.

Unfortunately the species had not, at that time, been critically studied, and in a final revision at a later period (1880) it became necessary to make an arrangement of the genera and species which is not in accordance with the arrangement upon these plates. In the course of the work it has been found necessary to reproduce, in a more correct form, with illustration of the parts, some of the figures of the earlier plates, as well as to give many additional species. All these later illustrations are given on Plates lxxxi-xeii inclusive, which are arranged in systematic order, with the generic forms in their natural relation to each other. It is to be regretted that these plates cannot be arranged in consecutive order with those preceding, but in the earlier part of the work the

plates were lithographed, from i to lxxx, for illustrating the material then on hand, and the additional plates can only come in after the latter number. This want of conformity, however, affects only the plates, the text presenting the genera and species in consecutive and systematic order, with cross-references to the newly introduced plates.

The subdivision among those forms which have usually been referred to Aviculopecten was found to be imperatively necessary for any strict classification, and the other subdivisions among generic forms which have indiscriminately been referred to Avicula, Pterinea, Pteronites, etc., have been deemed equally important. In these subdivisions, while the essential internal characters have been regarded as of primary importance, the author, without violating this rule, has endeavored to make such an arrangement of the species that the student may determine the generic relations from the general form and exterior markings alone. Since the fossil Lamellibranchiata are commonly found in an imperfect condition, with the interior surface remaining attached to the matrix, and only in rare examples, or in very favorable conditions, revealing the interior structure, it becomes important to have some means of identification other than that furnished by the hinge characters which are so rarely accessible. However, notwithstanding the general arrangement according to external features, the hinge and the interior structure have by no means been undervalued or neglected, as is shown by numerous illustrations of these parts, which it is believed give an amount of information not before published in any work upon this class of fossils.

The synopsis of genera here presented is given without comment or comparison. In the succeeding volume the author proposes to give a résumé of all the genera described, and in the same connection a comparison with genera described in other publications with some notice of the bibliography of this class of fossils, so far as relates to the palæozoic forms. In that notice the reasons for the generic subdivisions proposed in the present volume will be given in full.

In the final revision of the genera and species and in the preparation of the

text and the later plates of this volume the author cheerfully acknowledges the very valuable assistance rendered by Mr. Charles E. Beecher.

Of the mechanical and artistic execution of this work I may speak with commendation. Regarding the scientific character of that part of the work already published and its value to the general public, we have had the testimony of prominent scientific men; and I hope the present volume may be regarded as an acceptable contribution to our knowledge of a class of fossils of which little systematic information has heretofore been given.

The author has been indebted for the use of specimens for study and illustration to Dr. James Knapp, of Louisville, Ky., to E. B. Knapp, Esq., of Skaneateles, N. Y., and to Mr. Charles E. Beecher. To the collections of the Cornell University he is indebted for two specimens illustrated in the present volume, and for several others which are illustrated in the plates already prepared for the next volume.

JAMES HALL.

Albany, February, 1884.

SYNOPSIS

OF THE

CHARACTERS OF THE GENERA

INCLUDED IN

THIS VOLUME.

. CLASSIFICATION.

Pectenidæ	Pernopecten. Crenipecten. Aviculopecten. Lyriopecten. Pterinopecten.	
Pteriniidæ	Pterinea. s. g. Vertumnia. Actinopteria. Ptychopteria.	inequivalve.
Aviculidæ	Limoptera. Glyptodesma. Leiopteria. Leptodesma. Pteronites. Palæopinna. Ectenodesma.	
Ambonychiidæ	{ Byssopteria.	
MYTILIDÆ	Mytilarca s. g. Plethomytilus. Mytilarca. Gosselettia. Modiola s. g. Mytilops.	equivalve.

Pernopecten,* Winchell. Shell like Pecten. Hinge with a central cartilage pit and a crenulated hinge-plate on each side below the hinge-margin. This and the following genus appear to be more nearly related to the genus Pecten than to Aviculopecten.

Crenipecten, Hall. Like Aviculopecten in form. Hinge furnished with a series of small cartilage pits throughout its entire length. Examples, pl. ix, figs. 12, 15.

Aviculopecten, McCoy, is emended to include those forms which have the hingeline usually shorter than the transverse diameter, and both ears well-defined. Test ornamented with rays. Example, pl. i, fig. 10.

Lyriopecten, Hall. Differs from the preceding in the short hinge-line and very small anterior ear. Test usually ornamented with strong rays. Example, pl. viii, fig. 8.

Pterinopecten, Hall. Hinge-line long. Ears not well-defined, being simple expansions or extensions of the upper lateral margins to the hinge-line. Test ornamented with rays. Examples, pl. ii, fig. 18; pl. v, fig. 6.

Pterinea, Goldfuss. Shell inequivalve, inequilateral; posterior side alate; anterior end nasute or auriculate. Ligament internal; ligamental area longitudinally striated. Cardinal teeth two or more. Lateral teeth linear oblique. Posterior muscular impression large, situated on the post-umbonal slope. Anterior muscular impression small, situated within the rostral cavity. Test ornamented with rays. Examples, pl. xv, figs. 1–21; pl. lxxxiii, fig. 12.

S. g. Vertunnia, Hall. Differs from Pterinea in having the right valve convex, and the left flat or concave. Hinge area narrow. Example, pl. xxiv, fig. 12.

Actinopteria, Hall. Characterized from Pterinea in the absence of a broad striated ligamental area and strong cardinal and lateral teeth. Right valve sub-convex. Surface with fine rays. Examples, pl. xvii, fig. 26; pl. xviii, fig. 13; pl. xix, fig. 3.

Ptychopteria, Hall. Differs from Actinopteria in the nasute anterior extremity, and large straight wing marked by a strong longitudinal fold. Hingeline narrow, linear; furnished with one or two linear oblique cardinal and lateral teeth. Surface with fine rays. Example, pl. xxiii, fig. 17.

^{*}See note, page 81.

Limoptera, Hall. Shell large, inequivalve, inequilateral, subquadrate, strongly alate on the posterior side, auriculate on the anterior end. Ligamental area large, common to both valves, wider in the left valve, longitudinally striate and extending to the cardinal extremities. The hinge has an oblique posterior tooth and several cardinal folds under the beak. Anterior muscular impression very small and deep, situated at the apex of the rostral cavity; posterior impression large. Pallial line simple, formed of a series of small deep pits. Inter-pallial area with numerous small pits for the attachment of umbonal muscles. Test radiated: radii becoming obsolete with age. Examples, pl. xcii, figs. 3, 8, 9.

Glyptodesma, Hall. Shell aviculoid, erect or moderately oblique; inequivalve. Ligament external. Ligamental area striated, continuous. Hinge with two strong lateral teeth, and numerous irregular transverse plications along the cardinal margin. In form the shells of this genus resembles Actinodesma; but it has not the permanent diverging teeth of that genus. Surface marked by concentric striæ. Examples, pl. xi, figs. 3, 4; pl. xiii, figs. 5, 10; pl. lxxxvi, figs. 3, 8.

Leiopteria, Hall. Shell aviculoid, oblique, sub-rhomboidal. Anterior extremity auriculate; wing large, extremity produced. Test without proper rays. Ligament external. Ligamental area marked by fine parallel longitudinal striæ. Hinge with one or two oblique slender lateral teeth. The cavity of the beak is partially separated from the anterior end by a short partition or diaphragm. Examples, pl. xx, fig. 17; pl. lxxxviii, figs. 5, 27.

Leptodesma, Hall. In its prevailing forms it is similar to Leiopteria, except that the anterior end is always nasute and acute instead of auriculate and rounded. Hinge narrow, furnished with a slender lateral tooth just posterior to the beak and nearly parallel to the hinge-line. Ligament external. Ligamental area narrow, extending the entire length of the hinge, marked by fine, sharp, longitudinal striæ. Test with concentric striæ. Examples, pl. xxi, fig. 14; pl. xxii, fig. 21; pl. xc, fig. 28; pl. xci, figs. 9, 16.

Pteronites, McCoy. This genus is restricted to those possessing the characters of the original types. Body very oblique. Hinge-line longer than the body

of the shell. Wing and hinge extended posteriorly. Test marked by concentric strice. Example, pl. xxii, fig. 26.

Palæopinna, Hall. Shell similar in outline to Pinna, gaping in front. Test marked by fine radiating lines. Body more convex and test with finer rays than in the ordinary Pinna. Hinge-line simple. Example, pl. xxv, fig. 18.

Ectenodesma, Hall. Resembles Glyptodesma in outline, except that the anterior wing is more produced and both wings more acute at their extremities. Test ornamented with rays. Example, pl. xxiii, fig. 30.

Byssopteria, Hall. Shell erect, equivalve. Alate posteriorly, truncate, and with a nasute projection in front. Surface radiated. Examples, pl. xxiii, figs. 21, 22; pl. lxxx fig. 11.

Mytilarca, s. g. Plethomytilus, Hall. Equivalve, mytiloid, gibbous. Shells with a finely striated ligamental area. Posterior side subalate. Hinge-line transverse. Lateral teeth small, oblique; no cardinal teeth have been observed. Test with concentric striæ. Examples, pl. xxx, figs. 5, 7; pl. xxxi, figs. 2, 3, 7.

Mytilarca, Hall. Shell equivalve, inequilateral and mytiliform with terminal beaks and short hinge-line, which is bordered by a flattened, longitudinally striated, ligamental area of greater or less extent. Cardinal teeth small, situated beneath the beak. Posterior teeth small and oblique, situated at the post-cardinal extremity of the hinge. Test free from radii, with a single known exception. Examples, pl. xxxii, figs. 9, 17, 19, 20.

Gosselettia, Barrois. Shell subtriangular, truncate on the anterior side, subalate on the posterior side. Ligamental area wide, longitudinally striate. Cardinal teeth strong, situated under the beak. Lateral teeth elongate. Surface marked by concentric striæ. Examples, pl. xxxi, figs. 10–16.

Modiola, s. g. Mytilops, Hall. The fossils of this genus resemble Modiola and Lithodomus in external form, and may also be compared with the fossil genus Myoconcha. Hinge-line narrow, oblique, extending about one-half the length of the shell. Beaks terminal. Examples, pl. xxxiii, figs. 16, 17; pl. lxxxvii, fig. 9.

INDEX

TO SPECIES DESCRIBED OR NOTICED IN THIS VOLUME.

LAMELLIBRANCHIATA

OF THE

UPPER HELDERBERG, HAMILTON, PORTAGE AND CHEMUNG GROUPS.

DESCRIPTIONS OF SPECIES.

AVICULOPECTEN, McCov.

Section a,

AVICULOPECTEN PRINCEPS.

PLATES I, FIGS. 10, II; V, FIGS. 18, 19, 23, 24; VI, FIGS. 1-9; XXIV, FIG. 7; AND LXXXI, FIGS. 13-17.

Monotis princeps, Conrad. Annual Report N. Y. Geolog. Survey, p. 117. 1838.

Avicula parilis, "Proceedings Acad. Nat. Sci. Phila., vol. 8, p. 239, pl. 112, fig. 9. 1842.

Compare Aviculopecten Sandushyensis, Meek. Proceedings Acad. Nat. Sci. Phila., p. 161. 1871.

" Aricula parilis, Conrad? Meek. Palæontology of Ohio, vol. 1, p. 197. 1873.

" A. pecleniformis, Conrad. Jour. Acad. Nat. Sci. Phila., vol. 8, p. 240, pl. 12, fig. 14. 1842.

Avieulopecten princeps, (Conrad) Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 5, figs. 18, 19, 23, 24; pl. 24, fig. 7. Jan., 1883.

Aviculopecten Sanduskyensis, (MEEK) Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 1, figs. 10, 11. Jan., 1883.

Shell large, obliquely broad-ovate; axis inclined more than 60° to the hingeline; length and height nearly equal, varying within moderate limits; anterior margin convex; the convexity increasing to the middle of the postero-lateral side, thence truncated and extending in a straight line to the beak, making an angle of from 30° to 40° with the hinge-line. Valves depressed; left valve regularly convex; right valve nearly flat, or very moderately convex.

Hinge-line straight, having a length of from two-thirds to more than three-fourths the length of the shell, and extending anteriorly as far as the antero-lateral margin with little variation. Beaks obtuse, rounded, anterior to the middle of the hinge. Umbo subtending an angle of about 130°.

Ears large, triangular; posterior one the larger, and defined by the abrupt slope of the side of the umbo, while the anterior ear is separated by a distinct sulcus; lateral margins concave, becoming convex at the hingeline. Byssal-sinus broad, rounded, well-defined and indicated on the ear by a sulcus extending to the extremity of the beak.

The right valve is flatter and proportionally broader than the left. The limits of the ears are clearly indicated by the rapid slope of the umbo, and the absence of strong radiating lines of ornamentation.

Test thin, marked by numerous regular alternating rays, which increase in number by interstitial additions, and become broader and stronger towards the margins. These radiating ribs are crossed by very fine, sharp strice of growth. On the ears the rays are nearly obsolete, and the lines of growth are sharper and stronger than on the body of the shell.

The internal mould preserves, in a subdued degree, the ornaments of the exterior, and shows a simple, continuous pallial impression, extending nearly parallel to the margins, and terminating in a large sub-ovate muscular impression, which is posterior to the middle of the shell. The cavity beneath the beak extends over the ligamental area at that point, forming the cartilage-pit. In young individuals the ligamental area shows three or four small furrows at the beak, extending towards the extremities of the hinge-line. Three of these furrows measure 2 mm. across. In larger and older individuals, this furrowed ligamental area is much more marked, having frequently a width of 5 mm., and extends the entire length of the hinge, showing more numerous furrows. At the beaks the furrows are bent slightly outwards, otherwise, with gentle undulations, they run parallel to the hinge line. This feature is a constant character in this and several other species, and is similar to that in many forms of Pterinea and Lyriofecten.

The dimensions of the shells of this species are very variable. Large

individuals have a height of 80 mm, with nearly equal length, and a hingeline of 50 mm. The gradation from this form is very gradual to those in which the height is equal to, or greater than, the length, and where the length of the hinge-line is nearly equal that of the shell.

This species differs from A. pecteniformis by the larger anterior ears, with more numerous and less prominent rays on the body of the shell. In specimens identified as A. Sanduskyensis the umbo is more inflated and obtuse, while the length is uniformly greater than the height. A. scabridus, which in some respects resembles this species, is clearly distinguished by its characteristic surface-ornamentation and the proportionally greater height of the valves.

This is one of the largest and the most abundant species in the lower and middle portions of the Hamilton group. It is very easily distinguished by the large ears with the furrowed ligamental area, full, obliquely ovate outlines, and characters of ornamentation. It first appears in the Upper Helderberg limestone in western localities. It is abundant in the lower beds of the Hamilton group, especially in the coarser shales of the eastern central part of the State; while it is rare in the upper soft shales of the group, and searcely ever seen in the western counties.

Mr. Conrad suggests the probable identity of this species with the subsequently described form, A. parilis. A careful comparison of a large number of specimens establishes this synonymy, and indicates the propriety of uniting this form with the A. pecteniformis, Conrad. Aviculopecten Sanduskyensis, Meek, which was afterwards referred by that author to A. parilis, Conrad? belongs to this species.

The apparent specific differences noted in the description of these three forms are neither constant nor well defined; nor even to be regarded as marking varieties. They are separately considered for the purpose of referring to the original descriptions, and to correspond with the original specimens, which are figured for two of the species. Farther investigation will probably show more satisfactory proof of the validity of the present conclusions. The original description of Mr. Conrad is as follows—loc. cit.:

"Monotis princeps.—Shell convex, depressed; ear small, emarginate; radiating striæ numerous; rugose, profound. Length about 3 inches.

"Locality, Cazenovia."

Mr. Conrad's description of Avicula parilis is as follows (Jour. Acad. Nat. Sci. Phila., Vol. VIII, p. 239. 1842):

"Avicula parilis, pl. 12, fig. 9.—Upper valve flat; lower valve plano-convex; surface with numerous, equal, filiform, prominent radii; wings angulated at tip, the anterior one most acute, and nearly equal in length to the posterior wing; apex not elevated above the hinge line; anterior, posterior, and basal margins forming an uninterrupted arched or rounded outline.

"Locality, Cazenovia, Madison county, New York. Upper Silurian shale.

- "A beautiful and common species, the larger valve much resembling a Pecten.
- "The Monoris princeps, of the Geological Reports of New York, is probably the same shell.

"The flat valve is represented on the plate."

Formations and localities. In limestone referred to the age of the Upper Helderberg group (Corniferous limestone), at Sandusky, Delaware, and near Columbus, Ohio; and also at the Falls of the Ohio.

In the coarser shales of the Hamilton group, at numerous localities in the eastern and central portions of the State; in the upper soft calcareous shales of the group at Moscow, Livingston county, N. Y., and very rarely in the western extension of the group.

AVICULOPECTEN PECTENIFORMIS.

PLATE I, FIG. 9.

Avicula pecteniformis, Conrad. Journal Acad. Nat. Sci. Phila., vol. 8, p. 240. 1842.

Avicutopecten pecteniformis, (Conrad) Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations; Pl. 1, fig. 9. Jan., 1883.

SHELL sub-ovate oblique to the hinge-line; length equal to the height; anterior and basal margins regularly rounded, the body of the shell extending in a nearly straight line from the postero-lateral margin to the beak.

Left valve convex, reaching its greatest convexity at about one-third the length of the valve from the beak.

Hinge-line straight, having a length of more than two-thirds the length of the shell. Umbo prominent, sloping rapidly to the ears; the sides subtending a little more than a right angle. Beak prominent, situated a little anterior to the middle of the hinge.

Ears triangular, unequal, the anterior about one-half the size of the posterior one, lateral margins concave.

Right valve not observed.

Test ornamented by about 35 sharp, strong rays, with intermediate finer ones, which are crossed by fine imbricating strike of growth. The radii are not present on the ears. Internal characters not shown in the specimen described.

The original of this species has a length of 47 mm, with an equal height. The hinge-line measures 27 mm. The specimen is somewhat imperfect at the extremities of the ears, and the posterior ear is not sufficiently extended in the figure.

This form may be distinguished from A. princeps by its smaller anterior ear, and less expansion at the base of the ears. The umbo appears more contracted, and in the single known specimen is more prominent. The principal radii are sharper and stronger, and the alternation of smaller ones more regular.

In A. exacutus, which resembles this form, the beaks are nearer the middle of the hinge-line, and the shell has a distinctly reticulate surface ornamentation, with the radii continued over the ears.

The specimen figured is the left valve, and is the original of Mr. Conrad's description, no other specimen having been observed.

Formation and locality. From the corniferous limestone of the Upper Helderberg group, Schoharie, N. Y.

AVICULOPECTEN CLEON.

PLATE I, FIG. I.

Ariculopecten Cleon, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. I, fig. 1. Jan., 1883. Compare with the young of A. princeps.

Suell small, ovate; transverse axis slightly oblique; length somewhat greater than the height; margins regularly rounded.

Left valve convex, the convexity equal to about one-sixth the length of the hinge-line. The point of greatest convexity is just anterior to the centre of the shell and towards the beak. Right valve not observed.

Hinge-line straight, length five-sixths the height of the entire shell.

Beak anterior to the middle of the hinge, not prominent.

Ears defined by the absence of radiating lines, but not by any marked change in the convexity of the shell; lateral margins concave. The anterior car is limited by a shallow groove. The posterior car is about twice the size of the anterior.

Test thin, ornamented by a reticulation of fine radiating lines, and finer concentric strike of growth. The stronger rays have one or two finer lines between. The lines of growth extend over the ears, but less distinctly than over the body of the shell; and otherwise the ears are nearly smooth.

Interior not observed in the specimen described.

The length of this specimen is 21 mm., height 24 mm., hinge-line 20 mm.

This form resembles the young of A. princeps, but it is less oblique, and the ears less strongly defined than in the young of that species as represented in authentic specimens. The figure does not quite represent the form of the specimen, and the posterior ear is not so well defined as is shown in the illustration. The form A. exacutus is very similar to this one; but that species has fewer and sharper radiating striæ, and the geological horizons of the two are widely separated.

Formation and locality. Upper Helderberg limestone, Columbus, Ohio.

AVICULOPECTEN SCABRIDUS.

PLATE III, FIGS, 3-12.

Aviculopecten scabridus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 3, figs. 3-12.

Jan., 1883.

SHELL large, sub-circular, very slightly oblique to the hinge-line; length somewhat greater than the height; pallial margin circular, becoming very full posteriorly.

Valves depressed, moderately convex.

Hinge-line straight; length equal to two-thirds the length of the shell, marked by a thickening and inflection of the cardinal margins of the ears.

Beaks obtuse, rising slightly above and arching over the hinge-line, situated just anterior to the middle; umbonal angle 110°.

Ears narrow, triangular, indented by a sinus which has a depth equal to the width of the ears. The anterior ear of the left valve is one-half the width of the posterior, but of nearly equal length; in the right valve the ear is larger, and has a well-marked byssal sinus.

The right valve is somewhat less convex than the left, but, with the exception of the deeper anterior sinus, is very similar in character.

Test ornamented by about sixty strong, rounded rays, with some smaller intermediate elevated lines, which are crossed by regular, prominent, sub-imbricating lamellæ of growth, about 1.5 mm. apart. On crossing the rays, the varices of growth are bent suddenly upwards and backwards, forming short semi-tubular spines. The strong rays are absent upon the ears, but the lines of growth are numerous, and sharper than over the body of the shell.

The specimens are mostly partial casts of the interior, preserving no traces of the muscular impression, pallial line, or hinge characters, but retaining strong evidences of the external ornamentation of the shell. See fig. 7, pl. 3. Numerous individuals have a height of 55 mm., with usually a slightly greater length. The length of the hinge-line in mature examples is about 45 mm.

This well-defined species is readily distinguished by the slight obliquity of the body of the shell to the hinge-line, and the marked characters of the surface. It differs from A. princeps and A. pecteniformis in having strong and regular concentric markings, while the rays in these species are much more acute, and the axis of the shell is usually quite oblique to the hinge-line. Specimens which preserve the exterior shell show very beautifully the short spinous processes of the concentric lamellae; as shown, of the natural size, in fig. 10, pl. 3. Examples of the species are abundant, and have a considerable vertical and horizontal range within the group in New York.

Formation and localities. In the shales of the Hamilton group, at Pratt's falls, and Delphi, Onondaga county; Ludlowville, Cayuga county; Bellona, Yates county; Geneseo, Livingston county, and other places in western New York.

AVICULOPECTEN EXACUTUS.

PLATE III, FIGS, 18-22.

Aviculopecten exacutus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 3, figs. 18-22. Jan., 1883.

Shell of medium size, obliquely broad-ovate; greatest longitudinal diameter below the middle; height nearly equal to the length, transverse axis oblique to the hinge-line; basal margin full and regularly rounded; posterior margin extended beyond the ear, and more convex than the anterior.

Valves equally convex; the byssal sinus larger in the right valve, and the umbo less ample.

Hinge-line straight, length four-fifths the longitudinal diameter, extending nearly as far as the anterior margin.

Beak obtuse, oblique, anterior to the middle of the hinge and of the valve; umbo ample. In some specimens of the left valve, the beak arches over the hinge-line, while in the right valve the beak rises from the hinge.

Ears triangular; posterior one somewhat the larger, margin concave, extremity acute; defined from the umbo by a broad, shallow sulcus, an obscure carination, and an abrupt change in the surface characters to sub-

dued striæ. The anterior ear is well-defined by the sulcus extending from the angular byssal sinus.

Test ornamented by about forty strong, sharp, continuous rays, alternating in size with broader and concave interspaces, crossed by fine, sharp, crenulating concentric striæ. The ears show finer concentric striæ and a few rays.

Pallial line impressed, continuous, extending parallel to the margin of the shell about half way from the beak, terminating near the centre of the posterior side, in a sub-circular, muscular impression, marked with regular concentric striæ. The east preserves traces of the exterior markings, but presents no definite characters of the hinge.

The largest specimen has a height of 35 mm. A medium-sized specimen has a height of 26 mm.; length 27 mm.; hinge-line 24 mm.

This species differs from the young of A. princeps, in its more acute beak, smaller anterior ears, and in having rays on both ears; the rays on the body of the shell are also stronger. It resembles A. formio in outline, but has more sharply elevated rays, and less strong concentric striæ. A. pecteniformis has obtuse rounded beaks, and ears not marked by rays, which are distinguishing features of that species.

Formation and localities. In the shales of the Hamilton group, Monteith's Point, Ontario county; and Hamburg, Erie county, N. Y.

AVICULOPECTEN FORMIO.

PLATE V, FIGS. 20, 21.

Ariculopecten formio, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 5, figs. 20, 21. Jan., 1883.

Shell of medium size, obliquely ovate, extended behind; length equal to or somewhat less than the height.

Valves depressed, slightly convex. The right and left valves are very similar; the right being somewhat less convex, and having finer surface markings.

 $^{\sim}2$

Hinge-line straight, extending as far as the anterior margin; length twothirds the height of the shell; ligamental area narrow.

Beaks well-defined, not rising above the hinge-line, situated anterior to the middle.

Posterior ear large, triangular, margin concave; the ornamentation differing from that on the umbo; defined by a slight depression and a change of convexity. Anterior ear small, defined by a well-marked sulcus; byssal sinus deep; margin convex near the extremity of the hinge-line. The area of the posterior ear is more than twice that of the anterior.

Test ornamented by about 35 rounded, radiating costæ, with intermediate smaller ones, crossed and crenulated by regular striæ of growth, of which there are about 10 in the space of 5 mm. On the ears the radiating lines are present, especially on the anterior ear, and the concentric striæ are more crowded than on the body of the shell.

The characters of the interior are not preserved.

The largest specimen has a length of 32 mm., and the hinge-line measures 23 mm. A smaller specimen, preserving both valves, has a length of 29 mm., and height about equal.

This species is distinguished from A. exacutus by the greater angle subtended by the sides of the umbo, by its greater obliquity, and the less sharp radiating costae of the surface. In A. Phorcus the length is comparatively greater and hinge-line shorter, the ears smaller, and the strong crenulating strice of growth do not occur.

Formation and localities. In the shales of the Hamilton group, at Fultonham, Schoharie county; and Hamilton, Madison county, N. Y.

AVICULOPECTEN PHORCUS.

PLATE V, FIG. 22.

Aviculopecten Phoreus, HALL. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 5, fig. 22. Jan., 1883.

Shell of medium size, obliquely ovate; height and length equal; anterior and basal margins regularly rounded, becoming more convex towards the middle

of the posterior side, and thence concave to the beaks, giving the shell an appearance of considerable amplitude behind.

Left valve regularly and moderately convex. The right valve is unknown. Hinge-line straight, about one-half the length of the shell.

Beak rounded, extending to and situated near the centre of the hinge-line; unbonal angle smaller than usual, being about 90°.

Ears comparatively small, triangular, with concave margins; posterior ear the larger, separated from the body of the shell by a difference in convexity and the absence of radiating lines; anterior ear defined by a sulcus.

Test marked by about 60 fine, rounded, radiating costae, with a few intermediate smaller ones, and fine strike of growth. The rays are absent on the ears, but the lines of growth are more distinct than on the body of the shell.

The characters of the interior have not been observed.

The specimen described has a height of 37 mm., and a greatest length of 26 mm.

This species differs from A. formio by its smaller ears, their distinct character, and the general surface-markings. It resembles young individuals of A. princeps; but the comparative size and extent of the ears are very different, while the body of the shell is more constricted at the base of the ears. A. fasciculatus is very similar in the general form of the body of the shell; but the length is greater than the height. The alæ and the ornamentation of the test are distinguishing characters.

Formation and locality. Hamilton group, Schoharie, N. Y.

AVICULOPECTEN FASCICULATUS.

PLATE V, FIGS. 9-17; AND PLATE LXXXI, FIGS. 1-4.

```
Aviculopecten fasciculatus, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 5, figs. 9, 10, 12, 16, 17. Jan., 1883.

Aviculopecten repletus, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 5, figs. 13-15. Jan., 1883.

"Orestes, " " " Pl. 5, fig. 11. " "
```

Shell obliquely and transversely ovate; height more than seven-eighths of the length, produced behind. Pallial margins regularly rounded, becoming more

convex towards the middle of the postero-lateral side, and extending in a straight or slightly concave line to the beaks.

Valves moderately convex, the right one more depressed when seen in connection with the other, shorter and comparatively less oblique.

Hinge-line straight, length nearly two-thirds the height of the shell; extending, in young individuals, as far as the anterior margins.

Beaks prominent, well-defined, situated anterior to the middle of the hinge-line. Umbo very convex.

Ears of the left valve triangular, the posterior one larger, more attenuate at the extremity, and defined by a sulcus; the margins concave from the rapidly sloping side of the prominent umbo. Ears of the right valve much narrower, and attenuate at the extremities, with fewer radiating lines, marked by a very deep byssal sinus.

Test ornamented with numerous filiform, radiating striæ, which are often fasciculate, and fine concentric lines of growth. The broad fascicles of striæ often extend across one interval of growth, and on the succeeding interval appear as regular or irregular striæ without aggregation, or as fascicles of finer striæ. This change does not always occur, but is very characteristic when seen, as in figure 17, plate 5, where the variation is so extreme that it affects the outline of the shell. In young specimens the rays are regular, with a slight fasciculate arrangement. The concentric lines are sharper and more crowded on the ears and the rays are more subdued.

Interior not observed.

One specimen has a height of 30 mm., and a length of 32 mm.; another specimen has a height of 23 mm., and a length of 25 mm.; the hinge-line is 16 mm.

The form and surface markings distinguish this species. It differs from A. formio, A. princeps and A. pecteniformis in its surface markings; and from A. princeps especially, by the presence of radii on the wings.

Several varieties were designated in the preliminary examination as A. repletus and A. Orestes; but a larger collection of specimens since these species

were indicated has demonstrated the identity of the several forms, notably figs. 14 and 15 of plate 5, which do not show a fasciculation of the striæ.

Formation and localities. In the shales of the Hamilton group, Schoharie, Onondaga and Madison counties; also occurring in boulders of the coarse shales of the Hamilton group at Chemung Narrows, N. Y.

AVICULOPECTEN IDAS.

PLATE III, FIGS. 1, 2; PLATE XXIV, FIG. 1.

Ariculopecten Idas, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations; Pl. 3, figs. 1, 2; 24, fig. 4. Jan., 1883.

Shell ovate-orbicular, transverse axis slightly oblique to the hinge-line; height nearly equal to or greater than the length; outline full in front, not extended posteriorly.

Right valve depressed; moderately convex. Left valve not observed.

Hinge-line straight, length less than two-thirds the length of the shell, extending farther towards the anterior than the posterior margin.

Beaks obtuse, well-defined, the umbo separated on each side from the ears by a distinct sulcus, which is more marked on the anterior side. The beaks are nearly in the centre of the hinge-line, but somewhat anterior to the middle of the shell.

Ears unequal. Anterior one about twice the size of the posterior, convex, margins convex; separated from the body of the shell by a deep sinus which is continued to the beak as a distinct sulcus. Posterior ear triangular, with margins concave.

Test thin, marked by fine, concentric lines of growth, and about 80 rounded, radiating striæ, which increase by interstitial addition, with the interspaces less than the striæ, of which there are from 7 to 9 in the space of 5 mm. at the pallial margin. The surface characters continue on the ears; but upon the posterior ear the radiating lines are very subdued, while on the anterior one they are quite prominent.

Interior characters not observed.

The largest specimen has a height and length nearly equal, and hinge-line

20 mm. Another individual has a height and length of 27 mm., and hingeline 16 mm.

This species differs from A. fasciculatus in its comparatively larger anterior and smaller posterior ears, while the shell is less full behind, and the fasciculate surface has not been observed. In A. formio the posterior ears are much larger, and the surface is distinctly reticulate. In A. scabridus the beaks are more rounded, the wings more extended, and the surface quite different. Some forms of A. duplicatus and A. rugastriatus resemble this species; but the posterior ears of those species are larger, the anterior pair wider, and the surface markings characteristic.

The specimen, figure 13, plate 7, from the Chemung group is very nearly related to this species. A careful examination reveals the following differences. A. Itys is less oblique in outline, radiating striæ less distinctly rounded, inclining to angular, distance between them greater than the striæ themselves; the evidence of the implantation of intermediate striæ is obscure; the concentric lines are more distant and sharper, leaving the radii in the cast distinctly crenulate.

Formation and localities. In the Hamilton group at Fultonham, Schoharie county; shore of Cayuga lake; and Darien, Genesee county, N. Y.

AVICULOPECTEN LAUTUS.

PLATE III, FIGS. 16, 17.

Aviculopecten lautus, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 3, figs. 16, 17. Jan., 1883.

Shell obliquely ovate, height equal to the length, valves depressed, convexity of right and left valves sub-equal.

Hinge-line straight, length about one-fifth less than the height of the shell, or in some specimens longer, extending as far as the anterior margin of the valve. Beaks depressed, obtuse, anterior to the centre of the hinge-line.

Ears sub-equal, triangular, flat, mucronate at the extremities, margins

concave except in the anterior ear of the right valve, which is convex; defined by the umbonal carinæ, and by the absence of rays on the posterior slope. Byssal notch in the right valve angular, deep, continuing to the beak as a sulcus which separates the ear from the umbo.

The right valve, though very similar to the left, is not so high, and the anterior ear differs in form from the corresponding one in the left valve.

Test thin, ornamented by about 90 sharp rays, with concave interspaces having an equal number of intermediate finer rays, and crossed by numerous regular, sharp concentric striæ. The markings on the ears are similar to those on the body, but less strong.

Ligamental area very narrow, and marked on the outer margin by an inflection of the test. The other characters of the interior are not preserved.

The left valve of one specimen has a height of 23 mm., length 24 mm., hinge-line 23 mm.; the right valve of the same has a height of 22 mm., and a length of 24 mm. A larger specimen is 29 mm. in height, with an equal length.

This species resembles A. exacutus in outline, but differs in the lesser convexity and obliquity of the valves; the beaks are not prominent, and the surface characters are finer and more delicate. Young individuals of A. scabridus may be distinguished from this species by the more rounded and obtuse beaks, and rugose rays, which are usually absent on the ears. A. formio differs by its obliquity and the inequality of the ears, and the much stronger striæ.

Formation and localities. In the shales of the Hamilton group, at West Bloomfield, Ontario county, and York, Livingston county, N. Y.

AVICULOPECTEN RUGLESTRIATUS.

```
PLATE VII, FIGS, 8-II; AND PLATE LXXXI, FIGS, 11, 42.
```

Lima rugastriata, Hall. Geolog, Surv. N. 7.; Rep. Fourth Dist., p. 264, 1843.

Ariculopecten rugastriatus, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations; Pl. 7, figs. 8-11.

Jan., 1883.

Suell longitudinally ovate, oblique, more convex in front; height one-fourth greater than the length; outline oblique-ovate, with the posterior margin

depressed convex; the anterior margin more convex, and the base abruptly rounded.

Valves convex, very similar, except that the right valve shows an acute byssal sinus.

Hinge-line short, straight, length more than one-half the length of the shell.

Beaks acute, prominent, anterior to the middle of the hinge.

Ears small, broad-triangular; posterior one a little the larger, margin slightly concave; anterior car defined by a distinct sulcus, which is narrow and deep in the right valve, margin convex; byssal sinus deep and acute. The posterior car is less distinctly limited in the right valve.

Test near the beaks ornamented by fine filiform rays, which are crossed and crenulated by sharp, concentric striæ. Below the middle of the shell the rays become large rounded plications, increasing by implantation or bifurcation, and the regular concentric striæ are stronger, distinctly erenulating the rays, becoming foliate, and giving the surface a rugose appearance. The rays and concentric lines are present on the ears.

The interior is not preserved.

Two left valves have a height of 35 mm., and 22 mm.; length 29 mm. and 18 mm.; the hinge-line 16 mm. and 10 mm. respectively. A right valve of nearly the same proportions has a height of 33 mm., length 25 mm., and hinge-line 17 mm.

This species is distinguished from A. duplicatus by its comparatively greater height, the obliquity of the valve, and the acute beaks; the surface characters of the two are very similar. A. cancellatus is more circular in outline, and the anterior cars are larger than the posterior pair.

Formation and localities. Shales of the middle Chemung group, Philipsburg, Rockville and Hobbieville, Alleghany county, N. Y.

AVICULOPECTEN DUPLICATUS.

PLATE VII, FIGS. 1-7; AND PLATE LXXXI, FIGS. 9, 10.

Pecten duplicatus, Hall. Geolog, Surv. N. Y.: Rep. Fourth Dist., p. 264, 1843.

Avieulopecten duplicatus, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 7, tigs. 1-7.

Jan., 1883.

Shell ovate-orbicular, sub-equilateral, height usually less than the length; greatest length below the centre of the shell, giving a somewhat truncated appearance to the base.

Valves moderately convex; very similar in dimensions and convexity; the central position of the beaks makes the valves nearly equilateral. The right valve is marked by a deep byssal sinus.

Hinge-line straight, central, length from more than one-half to two-thirds the length of the shell. Ligamental area narrow.

Beaks rounded, obtuse, sub-central. Umbo prominent, ample.

Ears small. Anterior larger and well-defined by the sulcus extending from the sinus to the beak. Posterior one small, triangular; margins concave. Byssal notch deep and abrupt.

Test ornamented with regular duplicating rays, which increase in strength towards the margins, crossed by fine, regular, foliate, concentric expansions of the test. In well-preserved specimens this character of surface gives a decided limate appearance, and somewhat resembles A. rugæstriatus. In weathered specimens this surface character is subdued to a reticulation and crenulation. Near the beaks the shell is nearly smooth; towards the margins it is sometimes marked by strong, rounded plications. The rays and concentric lines are continued over the ears, and the anterior ear usually has several stronger plications.

A right valve, somewhat larger than usual, has a height of 31 mm., length 35 mm., and hinge-line 20 mm. A medium example has a height of 27 mm., length 30 mm., and hinge-line 18 mm. Younger forms vary slightly from these proportions; a small left valve measures 23 mm. in height and length, with a hinge-line of 15 mm.

This species resembles A. rugastriatus in surface characters, but it is less oblique and proportionally much longer, with beaks more obtuse. The outline of A. cancellatus is more nearly circular, and the direction of the transverse axis is oblique. From A. scabridus it differs in its shorter hinge-line and smaller ears, as well as in the surface markings.

Formation and localities. In the calcareous shales of the middle Chemung group, Rockville, Hobbieville and Philipsburg, Alleghany county; East Randolph, Cattarangus county, N. Y.; and Mansfield and Sullivan, Tioga county, Pennsylvania.

AVICULOPECTEN CANCELLATUS.

PLATE VII, FIGS, 12, 14-19.

Pecter cancellatus, Hall. Geolog, Surv. N. Y.; Rep. Fourth Dist. 1843. Not Aviculopecter cancellatulus, McCoy.

Pecleu Halleanus,* D'Orbigny. Prodrome de Palæonfologie, vol. I, p. 87, No. 768. 1847.

Ariculopecten sub-cancellalus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 7, figs. 12, 14-19. Jan., 1883.

Shell small, broadly ovate, oblique, height a little greater than the length; anterior lateral margin full and rounded; posterior lateral margin, below the ears, gently curving.

Right valve regularly convex, sloping somewhat abruptly to the posterior ear.

Hinge-line straight, equal to two-thirds the length of the shell.

Beaks, anterior to the middle of the hinge-line, well-defined, obtuse.

Posterior ear small, undefined, the lateral margin concave, not projecting. Anterior ear marked by a deep sinus, with a sulcus extending to the beak; lateral margin rounded.

Test marked by fine, regular, rounded, radiating lines, crossed by regular sharp, concentric striæ, producing an evenly cancellate surface. The posterior car is marked by the concentric striæ with obscure radiating lines; the anterior car is rugose from the prominence of from four to six strong rays.

^{*}This name was proposed by d'Orbigny as a substitute for *Peeten cancellatus*, a name preoccupied by Phillips for an Oolitic fossil. The latter is probably a true Peeten, and there seems to me no sufficient reason why the original name may not be retained. *Avicata cancellata*, Phillips, Palæozoic Fossils, is probably not an Avicalopeeten.

Interior characters not known.

The original of this species is 20 mm, in height, 19 mm, in longitudinal diameter, and the length of hinge-line 12 mm. Another specimen is 14 mm, in height and 12 mm, in length.

This species is distinguished from A. duplicatus and A. rugæstriatus by the less rugose surface, smaller size and different outline. The form of the ears and byssal sinus is very similar to A. duplicatus, but differs in the regular reticulate surface; that species is also a comparatively longer shell. It is in shape more like A. rugæstriatus.

Formation and localities. In the middle members of the Chemung group, at Philipsburgh and Rockville, Alleghany county; Conewango, Cattaraugus county; and near Westfield, Chantanqua county, N. Y.

AVICULOPECTEN ÆQUILATERALIS, n. sp.

PLATE LXXXII, FIG. 1.

Shell of medium size, transversely ovate, erect, equilateral; height equal to the length; lateral and basal margins regularly rounded; upper anterior and posterior margins extending in nearly a straight line to the beak.

Left valve slightly convex; greatest convexity on the umbo.

Hinge-line straight, nearly two-thirds the length of the shell, situated centrally.

Beak well-defined, situated near the centre of the hinge-line.

Ears sub-equal, triangular, defined from the numbo by a sinus in the margin, with a sulcus extending to the beak; margins slightly convex; extremities rounded.

Test ornamented with about sixty regular, straight, alternating rays, crossed by fine, irregular strike of growth. The rays are present on the ears, and are more numerous on the anterior ear.

The specimen described has a length and height of about 38 mm., and hinge-line of 22 mm.

This species is distinguished by its erect equilateral form, sub-equal ears, and the strong, regularly alternating radii.

Formation and locality. In the upper beds of the Chemiung group at Alleghany Sulphur Springs, Warren county, Pa.

AVICULOPECTEN ITYS.

PLATE VII, FIG. 13.

Aviculopecten Itys, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations; Pl. 7, fig. 13. Jan., 1883.

Shell small, broadly ovate, length nearly equal to the height, slightly oblique; margins regularly rounded, nearly equilateral.

Right valve depressed-convex. Left valve not known.

Hinge-line straight, sub-central, having an extent of a little more than one-half the greatest length of the shell.

Beak acute, directed slightly forward. Posterior umbonal slope making a greater angle with the hinge-line than the anterior. Umbo subtending a right angle.

Ears nearly equal. Anterior ear the larger, obtuse at the extremity, marked by several strong radii, separated from the umbonal region by a strong sulcus. Posterior ear narrow, triangular, margin concave, separated by a distinct sinus from the body of the shell, with no rays of ornamentation; obtuse-angular. Byssal sinus well-defined.

Surface marked by sub-angular, rounded radii, which are regularly increased in size with the growth of the shell, but rarely increased in number by implantation; concentrically marked by fine, regular, thread-like strike of growth.

Interior characters unknown. Hinge margin apparently simple.

The specimen described has a length of 25 mm., height 27 mm., hingeline 13 mm.

This species is less oblique than A. Idas, the hinge-line shorter, radii not present on the posterior ear, surface markings coarser; and rays increasing more rapidly in size though fewer in number. In A, caucellatus ($\Longrightarrow A$, Halleanus,

d'Orbigny), the valve is more convex, beak more obtuse, and the concentric marking forms a prominent feature.

Formation and locality. In the Chemung group at Conewango, Cattaraugus county, N. Y.

AVICULOPECTEN PLENUS.

PLATE XXIV, FIG. 3,

Aviculopecten plenus, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 24, fig. 3. Jan., 1883.

Suell sub-orbicular, sub-equilateral; transverse axis nearly vertical to the hinge-line; height one-sixth less than the length, giving a marked fullness to the outline of the sides.

Left valve convex, the convexity equal to one-sixth the length of the shell. The point of greatest convexity distant one-third the length from the beak. Right valve not observed.

Hinge-line straight, nearly central, the length more than two-thirds the length of the shell.

Beak obtuse, situated centrally with regard to the hinge-line, and also to the body of the shell; umbo rounded.

Ears sub-equal, triangular. Posterior car mucronate at the extremity; margin deeply concave. Anterior car acute at the extremity, and the margins convex; separated from the umbo by an abruptly sloping sulcus extending to the beak.

Surface ornamented with about 130 regular, rounded, close, filiform radii, crossed by very fine, sharp, concentric striæ. The surface markings are present on the ears, the radii distinct and stronger than on the adjacent portions of the shell. The rays become more frequent and finer from the basal margin in both directions towards the ears.

Interior not preserved in the specimen described.

The height of the specimen is 25 mm., length 30 mm., hinge-line 21 mm. On the lower margin there are 9 rays in the space of 5 mm.

In form, this species bears considerable resemblance to A. duplicatus; but the surface markings are quite different, and the extremities of the hinge line are more acute in this species. In A. scabridus the beak is not so well defined, the ears usually more extended, and the coarser rugose radii of that species are characteristic. This form resembles some varieties of A. fasciculatus in the surface characters, but differs in the obliquity of the shell and form of the ears. It differs from A. Idas in the more round form, more numerous and elevated rays, and larger ears.

The single valve described appears to be well distinguished from all the other species, and possesses characters too remote to be united with any of those described from right valves alone.

Formation and locality. In arenaceous shales of the middle Chemung group, near Elmira, N. Y.

AVICULOPECTEN STRIATUS.

PLATE X, FIGS. 3, 4.

Pecten striatus, Hall. Geolog. Surv. N. Y.: Rep. Fourth Dist. 1843.

Aviculopecten striatus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 10, figs. 3, 4.

Jan., 1883.

Shell transversely ovate, scarcely oblique, nearly equilateral, width somewhat greater than the length.

Hinge-line straight, two-thirds the length of the shell, situated centrally in regard to the body of the shell, not extending as far as the margin.

Beak central to the hinge-line, well-defined, arching over the hinge; umbo prominent, the sides subtending a right angle.

Ears sub-equal, triangular, defined by the rapid slope of the sides of the umbo. Anterior ear the larger, limited by a broad sinus; margins slightly convex; extremity rounded. Posterior ear acute at the extremity; margins concave.

Test ornamented with fine, rounded, closely arranged, regular radiating striae, from 12 to 14 in the space of 5 mm. at the pallial margin. Some specimens show a slight flattening of the rays and also fine lines of growth. The ears present the same surface characters.

Ligamental area narrow, well-marked, its width is .5 mm, in a specimen of 20 mm, in height.

The original specimen of this species is 20 mm, in height, 18 mm, in length, and the hinge-line 13 mm. Another specimen is 13 mm, in height, 11 mm, in length, hinge-line 8 mm. The largest specimen found has a height of 22 mm.

This species resembles A. celsus more nearly than any other form here described; it differs from that one by its much smaller ears with concave margins, more obtuse umbo, regular, equal striæ, and comparatively shorter form. The two species agree in the non-obliquity of the body of the shell to the hinge-line. This species has a vertical range from the middle to the upper members of the Chemung group, but is not abundant.

Formation and localities. In the Chemung group at Painted Post, Steuben county; Chemung Narrows, Tioga county, N. Y.; and in Bradford, Tioga and Warren counties, Pennsylvania.

AVICULOPECTEN CELSUS.

PLATE VII, FIGS. 29, 30.

Aricutopecten altus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 7, figs. 29, 30, Jan., 1883.

Not Aricutopecten altus, White. Bull. U. S. Geol. Surv., vol. v, p. 110, 1879.

SHELL small, ovate cunciform, sub-equilateral, not oblique; height one-fifth greater than the length; pallial margin rounded to near the ears, where the sides of the shell are nearly straight.

Right valve convex; the greatest convexity being equal to one-fourth the length of the hinge-line. Left valve not observed.

Hinge-line straight, length three-fourths the length of the shell, not extending as far as either lateral margin.

Beak acute, straight, extremity pointed, arching over the hinge-line; umbo prominent, subtending an angle of 80°.

Ears broad-triangular, large, flat, sub-equal, the margins slightly convex; extremities rectangular; separated from the body of the shell by a moderate

sinus, and from the sides of the umbo by a sulcus; the byssal sinus is deep and rounded.

Test marked by fine alternating filiform radiating striæ, which are absent on the ears, except as two or three alternating undulations. Fine lines of growth mark the test and extend over the ears.

Ligamental area linear and marked by an inflection of the hinge-margin.

The specimen has a height of 15 mm, and a length of 13 mm, hingeline 10 mm. About 13 rays occupy the space of 5 mm, measured near the basal margin.

This form may be distinguished by its equilateral proportions, acute, straight apex, the non-obliquity of the transverse axis to the hinge-line, the broad, triangular ears and the alternating surface striæ. These characters separate it from A. striatus, to which it is most nearly allied.

Formation and locality. In sandstone of the conglomerate, associated with the upper Chemung group, at Salamanca, Cattaraugus county, N. Y.

AVICULOPECTEN PATULUS.

PLATE VII, FIGS, 32, 33.

Aviculopecten patulus, Hall. Pal. N. V., vol. v. pt. 1. Plates and Explanations: Pl. 9, figs. 32, 33. Jan., 1883.

Shell large, longitudinally broadly elliptical; height about five-sixths as great as the length. The axis of greatest height is at right angles to the hinge, and the line of greatest length is parallel to the hinge and across the middle of the shell. Basal margin convex, somewhat tlattened in the middle. Lateral margins very full, and curving rapidly to the ears.

Valves convex, the convexity equal to one-fourth the length of the hingeline. The right and left valves do not differ conspicuously in character, so far as observed.

Hinge-line apparently straight, equalling nearly two-thirds the length of the shell, central, not extending as far as either lateral margin. Beaks obtuse, rounded; umbo prominent, straight, central, well-defined by its gibbous form and the rapid slope of the sides. Umbonal angle 110°.

Ears broad-triangular, sub-equal, separated from the body of the shell by a broad, deep sinus; margins concave below, becoming convex above the middle; extremities rounded.

Test ornamented by regular, sharp radii, with broader concave interspaces, and some finer radii, crossed by irregular crenulating lines of growth. Near the basal margin of a large specimen, there are five of these rays in the space of 10 mm. A smaller specimen has eleven rays in the same space.

The interior is not preserved.

The measurements of one individual are: height 55 mm., length 69 mm., hinge-line 41 mm.; of another specimen, height 26 mm., and length 30 mm.

This species nearly resembles in form A. ellipticus, and differs by its sharp, crenulated radii, while that species is marked by strong, rounded, continuous plications; and the hinge-line is comparatively somewhat longer. These two forms differ from others in their broad longitudinally elliptical outlines, and the amplitude of the umbones.

Formation and locality. In conglomerate and sandstone, associated with the Upper Chemning group, at Rock City, near Salamanea, Cattaraugus county, N. Y.

AVICULOPECTEN ELLIPTICUS.

PLATE VII, FIG. 31.

Aviculopecten ellipticus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 7, fig. 31. Jan., 1883.

SHELL large, longitudinally broadly elliptical, equilaterial, not oblique; height equal to about four-fifths of the length; margins regularly convex and rapidly curving to the beak.

Left valve capacious, convex. Right valve not observed.

Hinge-line straight, central, length equal to about one-half the length of the shell.

Beak straight, central, obtuse, rounded; umbonal angle about 110°.

Ears sub-equal, broad-triangular, flat; margins slightly convex; extremities rectangular, defined by a gentle sinus, which is deeper below the anterior ear.

Test marked by about 35 strong, rounded, radiating continuous plications which are wider than the interspaces. These radii are absent on the ears. The strike of growth are irregular and mark the entire surface of the shell.

Internal characters not observed.

A large specimen has a height of 53 mm., length 66 mm., hinge-line 34 mm.

This species differs from A. patulus in its shorter hinge-line, and the strong rounded radiating plications.

Formation and locality. In sandstone of the upper part of the Chemung group at Meadville, Crawford county, Pennsylvania.

AVICULOPECTEN DOLABRIFORMIS.

PLATE VII, FIG. 21.

Pecten? dolabriformis, Hall. Geolog. Surv. N. Y.: Rep. Fourth Dist., p. 265. 1843.

Aviculopecten dotabriformis, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 7, fig. 21.

Jan., 1883.

Shell small, sub-orbicular, slightly oblique; height nearly equal to the length; margins regularly rounded, becoming more inflated and convex posteriorly.

Right valve moderately convex. Left valve unknown.

Hinge-line straight, central, more than two-thirds the length of the shell.

Beak central, straight, obtuse, rounded, not rising above the hinge-line; umbo well defined by the rapid slope of the sides and the flatness of the ears.

Ears triangular, flat; margins slightly concave; extremities obtuse-angular. Posterior ear of the right valve about one-third larger than the anterior. Byssal sinus not marked.

Test cancellate, marked by fine radii and concentric striæ, which characters are also preserved on the ears.

Internal characters not known.

A right valve has a height of 11 mm., length 12 mm., and hinge-line 8 mm.

This small species somewhat resembles A. squama in the form of the body and surface markings, but the beak is less acute and the anterior car comparatively smaller, without distinct sinus.

Formation and locality. In the arenaceous shales of the Cheming group at Philipsburg, Alleghany county, N. Y.

AVICULOPECTEN SQUAMA.

PLATE VII, FIG. 20,

Aviculopecten squama, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 7, fig. 20. Jan., 1883.

Shell transversely broad-elliptical, slightly oblique; height about nine-tenths of the length.

Right valve moderately convex. Left valve not known.

Hinge-line straight, length two-thirds the length of the shell, extending in front as far as the anterior margin of the valve.

Beak rounded, not rising above the hinge-line, situated posterior to the centre; umbonal angle 90°.

Posterior ear small, triangular, narrow, with concave margin; not strongly defined; extremity angular. Anterior ear large, convex, broad-triangular; extremity obtuse; margin convex; separated from the body by a deep rounded sinus, and from the sides of the umbo by a distinct sulcus.

Test marked by very fine radiating striæ and irregular lines of growth.

These surface characters extend also over the ears.

Internal characters not known.

The specimen described is 11 mm. in height, 12.5 mm. in length, and hinge-line 8 mm.

This species differs from A. dolabriformis in its more acute beak, absence of regular concentric striæ, and much larger anterior ear.

Formation and locality. In the Chemung group at Philipsburg, Alleghany county, N. Y.

AVICULOPECTEN CONVEXUS.

PLATE VII, FIGS. 22, 23.

Pecten? convexus, Hall. Geolog. Surv. N. Y.: Rep. Fourth Dist., p. 265. 1843.
Aviculopecten convexus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 7, figs. 22, 23.
Jan., 1883.

Shell small, sub-orbicular, not oblique; height somewhat greater than the length; margins regularly rounded.

Left valve very convex, convexity equal to about one-third the length of the shell. Right valve not known.

Hinge-line straight, central, length three-fifths the length of the shell.

Beak prominent, straight, central, rounded, arching over the hinge-line; the sides of the umbo subtend a right angle.

Ears broad-triangular, extremities obtuse-angular. Posterior ear of left valve smaller than the anterior, defined by the abrupt slope of the umbo; margin slightly concave. Anterior ear convex; margin straight; separated from the umbo by a very deep and narrow sulcus. Byssal sinus small.

Test marked by fine irregular radiating striæ and finer regular concentric lines; the same surface characters are continued over the ears. The specimen is exfoliated and the radii represented in the figure are partially restored.

Interior characters unknown.

The original of this species has a height of 12.5 mm., length 12 mm., and hinge-line 8 mm.

The remarkable convexity of the left valve distinguishes this species from all the other forms here described. Its orbicular outline, prominent beak and deep anterior sulcus are also characteristic. In general appearance the body of the shell resembles some forms of Athyris and Meristina among the Brachiopods, but its pectinoid character is well marked.

Formation and locality. In the shales of the Chemung group at Rockville, Alleghany county, N. Y.

AVICULOPECTEN SIGNATUS.

PLATE VII, FIG. 24,

Avicula? signata, Hall. Geolog. Surv. N. Y.: Rep. Fourth Dist., p. 265, 1843, Aviculopeden signatus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 7, fig. 24. Jan., 1883.

Shell small, obliquely sub-elliptical, the longest diameter making an angle of about 45° with the hinge-line; height and length nearly equal.

Left valve depressed, slightly convex. Right valve unknown.

Hinge-line straight, length more than two-thirds the length of the shell, extending in front as far as the anterior margin.

Beak very obtuse, rounded, depressed, directed forward, situated near the centre of the hinge.

Ears triangular, sub-equal, tlat. Anterior car separated from the umbo by a sulens; margin convex; extremity rounded. Byssal sinus moderately deep. Posterior car not well-defined; margin slightly concave; extremity obtuse-angular.

Test conspicuously marked by fine, regular, lamellose concentric lines, and a few irregular, radiating, indented striæ.

Interior characters not observed.

The original of this species is 11 mm, in length and height; the hingeline 8 mm.

This species is distinguished by the oblique, elliptical outline of the body of the shell, the depressed, obtuse beak, and the well-defined concentric striæ.

Formation and locality. In the Chemung group at Rockville, Alleghany county, N. Y.

AVICULOPECTEN CAROLI.

PLATE IX, FIG. 5

Aviculopecten Caroli, Winchell. Proceedings Acad. Nat. Sci., Phila. 1863.

Aviculopecten Caroli, (Winchell) Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 9, fig. 5, Jan., 1883.

SHELL small, sub-circular, not oblique, length and height equal; basal margin regularly rounded.

Left valve convex, the convexity equal to about one-sixth of the longitudinal diameter. Right valve unknown.

Hinge-line straight, length three-fourths of the diameter, extending nearly to the anterior margin of the shell.

Beak obtuse, prominent, central, rising above the hinge.

Ears triangular, nearly equal, separated from the umbo by distinct sulci. Anterior ear with slightly convex margin; extremity rounded. Byssal sinus deep. Margin of posterior ear concave; extremity abruptly mucronate.

The test (as preserved on a partial cast of the interior) is marked by about 45 regular alternating, rounded rays with equal interspaces. The lines of growth are fine and obscure on the specimen. The ears are marked by from five to eight rays similar to those on the body of the shell.

The ligamental area is a linear furrow along the hinge-line; cartilage pit small, situated under the beak.

The left valve described has a height of 17 mm., and an equal length; hinge-line 13 mm.

In the original description of this species mention is made of small, spinose processes from the concentric striæ; these do not exist in this specimen, which is a partial east of the interior.

This species is distinguished from A. striatus by its more circular form, obtuse beak, and stronger radii. Compared with A. elongatus, the wings are smaller, and the height comparatively much less.

Formation and locality. In the yellow sandstone of the Waverly group at Newark, Ohio.

AVICULOPECTEN (CRENIPECTEN?) INCULTUS.

PLATE IX, FIG. 3.

Aviculopecten (Crenipecten?) incultus, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl 9, fig. 3. Jan., 1883.

Shell small, longitudinally very broad-elliptical, nearly circular, not oblique to the hinge-line, sub-equilateral; height somewhat less than the longitudinal diameter; basal margin regularly rounded. Right valve depressed, convex. Left valve unknown.

Hinge-line straight, central, length one-half the length of the shell.

Beak obtuse, rounded, not rising above the hinge-line; sides of the umbo straight.

Ears small, sub-equal, narrow-triangular, separated from the sides of the umbo by sulci. Margin of posterior ear concave; extremity obtusely angular. Anterior ear defined by a deep, angular byssal sinus; margin convex; extremity rounded.

The external markings of the test are not preserved. The cast of the interior is nearly smooth. Pallial line faintly impressed. At each side of the umbo there is a shallow, undefined impression, nearly parallel to the margin, extending to about the middle of the length of the shell.

A specimen of the right valve has a height of 15 mm., length 17 mm., hinge-line 8 mm.

This species approaches very nearly several forms referred to Crenipecten. More perfect material may show the hinge to be crenulate, which character would exclude it from Aviculopecten.

Formation and locality. In conglomerate, referred to the Upper Chemung group, near Olean, Cattaraugus county, N. Y.

AVICULOPECTEN (PTERINOPECTEN?) INVALIDUS.

PLATE I, FIG. 18; AND PLATE LXXXII, FIG. 21.

Pterinoperten invalidus, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 1, fig. 18. Jan., 1883.

Shell small, rhomboidal; length and height nearly equal, moderately oblique; margins regularly rounded, full behind; the greatest posterior extension is below the middle.

Left valve depressed-convex. Right valve unknown.

Hinge-line nearly straight, length a little more than the length of the valve, and extending anteriorly.

Beak obtuse, rounded, situated just anterior to the centre of the hinge-line,

directed slightly forward, depressed. Umbonal region moderately prominent, subtending an angle a little less than 90°.

Ears triangular, flat, extremities acute. Anterior ear smaller, defined by a sulcus; margin nearly straight. Posterior ear with the margin coneave, extremity acuminate; having no strong radiating striæ.

Test, as indicated in an exfoliated specimen, marked by a few fine radiating striæ, with wider interspaces which are marked by finer radii. Anterior ear showing the same characters. Posterior ear free from rays. Fine concentric striæ cross the rays, and stronger concentric wrinkles interrupt them and produce a slight crenulation of the radii.

The specimen is 10.5 mm, in length, 10 mm, in height, with hinge-line a little more than 11 mm.

This species resembles in form the young of *Pterinopecten dignatus*, but differs in the finer radiating lines on the body of the shell, the concave margin, and absence of rays on the posterior ear.

Formation and locality. In the black Marcellus shale at Cherry Valley, Otsego eounty, N. Y.

AVICULOPECTEN (PTERINOPECTEN?) TERMINALIS.

PLATE I, FIG. 3.

Pterinopecten terminalis, Hall. Pal. N. Y., vol. v., pt. 1. Plates and Explanations; Pl. 1, fig. 3. Jan., 1883.

Shell small, rhomboidal; body of the shell obliquely ovate; length a little greater than the height; margins regularly rounded, somewhat extended behind.

Left valve very convex. Right valve unknown.

Hinge-line straight, central, equal to the length of the shell.

Beak acute, prominent, directed a little forward, arching over the hingeline. Umbo elevated, subtending a right angle.

Ears triangular; margins coneave; extremities acute. Posterior ear larger, undefined. Anterior ear limited by a shallow sulcus. Byssal sinus moderate.

Test thin, marked by fine sharp radii, with wider interspaces, which show one, two or three finer rays, crossed by fine crenulating lines of growth. The same characters of marking extend over the ears.

Internal characters not known.

The specimen is 14 mm, in length, 12 mm, in height, with hinge-line 15 mm.

This species, in surface markings, bears a slight resemblance to a young individual of *Aviculopecten princeps*; but the undefined ears and proportionally longer hinge-line distinguish it.

Formation and locality. In the upper layers of the Corniferous limestone; Young's farm, Williamsville, Erie county, N. Y.

Section b.

AVICULOPECTEN IGNOTUS.

PLATE I. FIG. 2.

Axiculopecten ignotus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 1, fig. 2. Jan., 1883.

Shell of medium size, transversely and obliquely sub-ovate; height about five-sixths of the length; margins regularly rounded, full on the anterior and posterior sides.

Left valve slightly convex, nearly flat. Right valve unknown.

Hinge-line straight, central, length nearly equal to the height of the valve.

Beak obtuse, rounded, low, directed toward the anterior.

Posterior ear large, broad-triangular, separated from the side of the umbo by a wide shallow suleus; margin slightly concave; extremity obtuseangled. Anterior ear less than one-half the width of the posterior, narrowtriangular, separated from the nmbo by a deep byssal sinus and a distinct sulcus, extending to the apex of the beak; margin convex; extremity rounded.

Test thin, about .5 mm. in thickness; marked with about twenty-five irregular, rounded radii, which are crossed by very fine concentric striæ, and occasionally interrupted by variees of growth. The rays are conspicuous

over the centre of the valve, becoming obscure toward the margins. The ears show the concentric striæ only.

The characters of the interior are not known.

A specimen of the left valve measures 25 mm. in height, 29 mm. in length, and the hinge-line 21 mm.

This species in general expression resembles A. tenuis, but is distinct in its smaller anterior ear, more obtuse beak, orbicular form, and more irregular and stronger rays. Their geological positions are widely separated.

Formation and locality. In soft shaly beds of the Corniferous limestone, which constitute the upper portion of the group, at Lapham's mill, near Victor, Ontario county, N. Y.

AVICULOPECTEN INSIGNIS.

PLATE I, FIG. 8; PLATE III, FIG. 13; AND PLATE LXXXI, FIG. 7.

Ariculopecten insignis, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations; Pl. 1, fig. 8; pl. 3, fig. 13. Jan., 1883.

Shell less than medium size, sub-rhomboidal, moderately oblique, about one-third longer than high; basal margins rounded; anterior and posterior margins obtusely angular or abruptly rounded, and extending along the cardinal slopes in a direct line to the beak.

Both valves are quite convex; right valve somewhat the less convex.

Hinge-line straight, nearly equal to the length of the shell.

Beak obtuse-angular, prominent, directed forward, nearly central. Umbonal region ample, the sides subtending an obtuse angle, and sloping more abruptly to the anterior than to the posterior margin.

Ears sub-equal, triangular. Anterior ear concave or flat, defined by a distinct sulcus; margin deeply concave; extremity acuminate. Byssål sinus deep and well-marked. Posterior ear flattened, defined by the absence of the stronger radii; extremity slightly acute; margin concave.

Test thin, marked by strong radiating costæ, which in the left valve are abruptly elevated and increase by interstitial addition; crossed by infrequent

elevated thread-like concentric crenulating striæ, which sometimes give a nodose character to the radii, and by finer lines of growth. The right valve is marked by rounded rays arranged in pairs, bifurcating on the umbo, crossed by fine concentric lines of growth. The radiating striæ are obscure on the ears, being more strongly marked on the anterior one.

The interior characters have not been observed.

The largest specimen has a length of 27 mm., height 20 mm., hinge-line 23 mm. A smaller specimen of 18 mm, in length has a hinge-line of precisely the same length.

The specimen figured on plate 1 is a young individual and does not well show the characters of the species which are better seen on the other figures referred to. See plate 81, fig. 7.

This species is less oblique, and the extremity of the posterior ear is less mucronate than in A. bellus and A. ornatus. The surface markings are very similar to the former, but quite distinct from the latter.

Formations and localities. In limestone above the Marcellus shales, at Stafford, Genesee county; in the softer shales of the Hamilton group at Moscow, Livingston county; and at Hamburgh, Erie county, N. Y.

AVICULOPECTEN BELLUS.

PLATE H, FIGS 5, 6, 9; AND PLATE LXXXI, FIG. 8,

Avicula bella, Conrad. Annual Geolog. Rep. N. Y., p. 54. 1841.
 Aviculopecten bellus (Conrad), Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 2, figs. 5, 6, 9. Jan., 1883.

SHELL small, longitudinally sub-elliptical; height equal to two-thirds or three-fourths of the length; margins regularly rounded.

Valves moderately convex; the right valve somewhat shallower than the left; very similar in form and ornamentation.

Hinge-line straight, the length a little greater than the longitudinal diameter of the shell, nearly central, extending equally beyond the posterior and anterior margins.

Beaks obtuse-angled, directed forward, placed anterior to the middle of the valve; sides of the umbo carinate, and descending abruptly to the ears.

Posterior ear flat or concave, narrow-triangular, well-defined by the carinate sides of the umbo, and by the absence of the strong surface radii; margin concave; extremity acute, mucronate. Anterior ear about two-thirds as long as the posterior one, triangular, convex; defined by a deep sulcus, and the angular cardinal slope of the umbo; margins of the ears in the left valve straight or concave; in the right valve, convex; extremities acute-angled. In the left valve the byssal sinus is broad and rounded; in the right valve it is a deep, angular notch.

Test of the left valve marked by from 40 to 50 regular, continuous, threadlike rays, alternating in fours, with three degrees of prominence, crossed and crenulated by fine, regular, concentric striæ. The surface of the right valve is nearly the reverse of this, having broad, flattened rays, arranged in pairs, regularly bifurcating, with narrow concave interspaces which correspond to the rays of the opposite valve. The posterior ears show several delicate rays extending from the apex of the beak over their upper portion.

The interior is not known.

A specimen preserving both valves has a height of 14 mm., length 19 mm., and hinge-line 20 mm. A right valve has a height of 14 mm., length 22 mm. A left valve has a height of 12 mm., length 16 mm., hinge-line 17 mm.

This species in appearance resembles A. ornatus, and differs in its longitudinally narrower outline, more obtuse beak, the numerous rays, and the absence of strong, lamellose, concentric fimbriæ. The two forms are of a group resembling several species in a parallel group of the genus Actinoptera, which are remarkable as possessing an aviculoid character (when compared with some recent species of Avicula); in the strong rays, the deep anterior sulcus and byssal sinus separating the anterior ears from the body of the shell.

Formation and localities. In the soft shales of the Hamilton group at Tinker's Falls, Onondaga county; Bellona, Yates county; and near Norton's Landing, Cayuga lake, N. Y.

AVICULOPECTEN ORNATUS.

PLATE II, FIGS 7, 8; AND PLATE III, FIG. 11.

Avienlopecten ornatus, Hall, Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 2, figs. 7, 8; pl. 3, fig. 14. Jan., 1883.

Shell small, longitudinally oblique-ovate, sub-rhomboidal; length and width in the proportion of three to four; margins regularly rounded.

Valves depressed-convex; left valve somewhat more convex than the right, and a little larger.

Hinge-line straight, slightly less than the length of the shell, central with regard to the body of the shell.

Beak obtuse-angular, directed forward, situated a little anterior to the middle.

Ears sub-equal. Posterior one the larger, triangular, flat or concave, defined by the abrupt post cardinal slope of the umbo; extremity acute; margin concave. Anterior ear defined by a deep sulcus; byssal sinus deep, more strongly marked in the right valve.

Test of the left valve ornamented by about 25 strong, sharp, elevated rays, and wide interspaces which are marked with a smaller ray; crossed by undulating, concentric striæ which are curved backwards between the stronger rays, producing arched fimbriæ. The right valve shows the radiating striæ originating near the umbo, which is smooth, and increasing by a double bifurcation, giving them a fasciculate appearance; they are crossed by undulating, concentric striæ. The ears are marked by strong, radiating lines and fine, concentric striæ.

Internal characters not observed.

The length of the largest specimen is 18 mm., height nearly 15 mm., and hinge-line about 17 mm.

This species, in form and general appearance, is very similar to A. bellus; it differs conspicuously in the ornamentation, with proportionally shorter posterior

ear. Both species show the smooth area on the umbo of the right valve; a character not observed in any other species here described.

Formation and locality. In the Hamilton group; shores of Canandaigua lake, Ontario county, N. Y.

AVICULOPECTEN MUCRONATUS.

PLATE III, FIG. 15.

Aviculopecten mucronatus, Hall. Pal. N. V., vol. v, pt. 1. Plates and Explanations: Pl. 3, fig. 15.

Jan., 1883.

Shell small, rotund-ovate, slightly oblique; length a little greater than the height. Basal and anterior margins regularly rounded; posterior margin full, abruptly sloping to the beak.

Left valve strongly convex. Right valve not observed.

Hinge-line straight, equal to the greatest length of the shell, extended anteriorly.

Beak obtuse-angular, directed forward, nearly central. Umbo deep, sides subtending an obtuse angle, sloping to the ears.

Ears sub-equal. Anterior car narrow-triangular, elongate, acuminate, defined by the deep byssal sinus and marked sulcus; margin concave. Posterior ear wider, limited by an undefined sulcus; margin concave; extremity acute.

Test ornamented by rounded radii, which bifurcate towards the margin; crossed by prominent, regular, concentric striæ.

Hinge-area simple.

The specimen has a length of 16 mm., height 15 mm., hinge-line 16 mm.

This species differs from A. insignis, A. bellus and A. ornatus in the following characters: the anterior ear is narrower, the outline of the shell is less oblique, and the form is more rotund.

Formation and locality. In calcareous shales of the Hamilton group at Dresden, Yates county, N. Y.

AVICULOPECTEN TENUIS.

PLATE VII, FIGS 27, 28; AND PLATE LXXXI, FIG. 6.

Aviculopeeten tenuis, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 7, figs. 27, 28, Jan., 4883,

Shell small to medium size, sub-orbicular, transverse axis oblique; length and height equal; margins regularly rounded, somewhat extended behind.

Left valve slightly convex, nearly flat. Right valve unknown.

Hinge-line straight, nearly central,; length five-sixths of the longitudinal diameter.

Beak directed forward, not rising above nor extending beyond the hinge, anterior to the centre of the hinge-line and of the valve. Umbonal angle 90°.

Ears large, broad-triangular, unequal, separated from the sides of the umbo by a broad, shallow sulcus. Anterior ear about one-half the size of the posterior, flat; margin convex; extremity obtuse-angular. Byssal sinus broad and comparatively shallow. Posterior ear marked by a low, convex undulation, adjacent and parallel to the sulcus; margin straight or slightly concave; extremity rectangular, pointed, more obtuse in mature specimens.

Test marked by about twenty-five strong, regular radii, with broader concave interspaces, and also, in well-preserved specimens, smaller intermediate rays. The specimens described are easts of the interior, and show but faint traces of concentric lines of growth. The ears are mostly free from surface markings.

Pallial line impressed, continuous, situated about one-half the distance between the apex of the beak and the pallial margin of the shell. Muscular impression elliptical, within the concavity of the valves adjacent to the sulcus of the posterior ear. Hinge-ligament without marked characters.

The largest specimen has a height of 29 mm., length 30 mm., and hingeline about 23 mm. A smaller individual is 23 mm. in height, 23.5 mm. in longitudinal diameter, and hinge-line measuring 19 mm.

This species resembles in some respects A. ignolus, and is distinguished by its transverse form, greater obliquity, larger anterior car in the left valve,

rectangular beak, and more regularly alternating rays. Both of these forms are remarkable for the very slight convexity of the left valve.

Formation and localities. In calcareous sandstone of the Upper Chemning group, Randolph and Salamanea, Cattaraugus county, N. Y.

LYRIOPECTEN, HALL.

Lyriopecten parallelodontus.

PLATE IV, FIGS, 1, 2,

Lyriopecten parallelodontus, Hall. MS. for Pal. N. Y., vol. v. 1877.

" " Catalogue Amer. Palæozoic Fossils, S. A. Miller. Cincinnati, 1877.

" " Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 4, figs. 1, 2.

Jan., 1883.

Shell of medium size, sub-orbicular, not oblique; height somewhat less than the longitudinal diameter; margins regularly rounded.

Right valve moderately convex. Left valve unknown.

Hinge-line straight; anterior portion not preserved in the specimen; from the beak to the extremity of the posterior ear its length is one-half the longitudinal diameter of the shell.

Beak obtuse, rounded, slightly oblique, anterior to the centre of the valve; umbonal region ample.

Posterior ear large, broad-triangular, flat; margin straight or slightly concave; extremity rectangular. Anterior ear not preserved.

Test thin, marked by about 90 regular, alternating, rounded radii, with concave interspaces, and crossed by fine, elevated, sharp, cancellating striæ; these are crowded over the posterior ear, and the rays are there more numerous and less regularly alternating.

The mould of the interior preserves, around the margin, traces of the stronger rays, and shows a moderately impressed pallial line, with apparently an ovate, muscular impression near the umbonal region. Cartilage-pit small, deeply indented. Ligamental area narrow, marked by two or three slender, parallel grooves, extending to the posterior extremity; and one or two

shorter, accessory grooves extending for a short distance from the cartilagepit, and parallel to the longer folds.

The specimen consists of the exterior and interior impression of a right valve; it is 38 mm, in height, 43 mm, in length, and the incomplete hingeline measures 20 mm, from the beak to the end of the posterior ear.

This species differs from L. orbiculatus in its comparatively greater length, the convexity of the right valve, and the regular alternation of the rays. It is remarkable as the only pectenoid form yet observed in the Schoharie grit, while similar forms are numerous in the Upper Helderberg limestone.

Formation and locality. In the Schoharie grit, Albany county, N. Y.

LYRIOPECTEN DARDANUS.

PLATE I, FIG. 5.

Lyriopecten Dardanns, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 1, fig. 5. Jan., 1883.

Shell of medium size, orbicular, transverse axis not oblique; height a little less than the length; margin regularly rounded.

Left valve moderately convex. Right valve unknown.

Hinge-line straight, length nearly equal to the transverse diameter of the valve, extending as far as the posterior margin.

Beak obtuse, rounded, straight, anterior to the middle of the hinge-line and to the centre of the longitudinal diameter.

Anterior ear small, narrow-triangular, flat, separated from the umbo by a broad, undefined sulcus; margin slightly convex above the sinus; extremity rectangular rounded. Posterior ear large, broad-triangular, flat; margin straight or slightly concave, rectangular to the hinge-line; extremity mucronate.

Test marked by about forty strong rounded continuous rays with wider, concave or flat interspaces, and sometimes a smaller intermediate ray; crossed by sharp, elevated concentric striæ. The rays are fine and little elevated on the ears, while the concentric striæ are conspicuous.

Interior characters not observed, except an indication of a well-defined ligamental area.

The specimen is 45 mm. in height, 48 mm. in length, and the hinge-line 43 mm.

This species resembles *L. parallelodontus*, but differs in the comparatively larger and more extended posterior ear and fewer and stronger rays, without regular alternation of size. *L. orbiculatus* is more elongate, with more numerous radii and less defined anterior ear.

The figure is from a gutta percha east of a mould of the exterior of the shell. Formation and locality. In the limestone of the Upper Helderberg group, Le Roy, Genesee county, N. Y.

LYRIOPECTEN ORBICULATUS.

PLATE IV, FIGS. 3-8; AND PLATE LXXXII, FIG. 3.

```
Aricula orbiculala, Hall. Geolog. Surv. N. Y.: Rep. Fourth Dist., p. 202. 1843.

Jan., 1883.

Not Axiculopecten orbicularis, McCov. Carb. Foss, of Ireland. 1844.

" " orbiculatus, " " " " "
```

Shell large, orbiculate, becoming wider and oblique with age; length and height equal in small and medium individuals; in large specimens the height is sometimes one-ninth greater than the longitudinal diameter; basal and lateral margins full and regularly rounded.

Left valve moderately convex; umbonal region ample. Right valve concave, flat or slightly convex over the umbonal region.

Hinge-line straight, central; length in young shells equal to four-fifths or five-sixths of the longitudinal diameter; and in large specimens the length is sometimes not more than one-half the length of the valve.

Beak obtuse, slightly oblique to the hinge, not rising above it, situated anterior to the middle of the hinge-line, and to the centre of the valve.

Anterior ear of left valve, in small shells, comparatively large, triangular,

limits not strongly defined; margin straight or slightly concave; extremity acute-angular; in older shells comparatively narrow, with an obtuse-angular extremity. Anterior ear of the right valve defined by a sulcus, extending to the extremity of the beak; margin convex; extremity rounded. Byssal sinus scarcely indicated on the left valve, forming a deep, angular noteh in the right valve. Posterior ear large, broad-triangular; length about two-thirds of the hinge-line; margin concave; extremity acute or right-angled in small specimens, obtuse in larger individuals; limits not defined.

Test thin, thickness nearly .3 mm., ornamented by about 80 rounded radii, with broader concave interspaces, crossed by regular, sharp, elevated, continuous, concentric, foliate expansions of the test, reaching an elevation of about .6 mm. above the general surface. Usually the test shows only the strong rays, with occasionally a reticulation (plate 4, fig. 8), where the concentric folds are only partially preserved. The figure cited represents also the internal mould where the test has been wholly removed.

Ligamental area, in young shells, represented by a slight inflection of the margin of the hinge with a very small longitudinal groove. In more mature specimens this area is wider, the number and strength of the grooves increasing, until they occupy a continuous space between the extremities of the hinge-line, slightly bending outwards at the beak; the inner ridges and grooves do not extend the whole length of the area. Cartilage-pit and muscular impressions not observed.

The original specimen of this species is 38 mm, high, 39 mm, long, hingeline about 30 mm. Another more nearly entire specimen is 35 mm, high, 37 mm, long, hinge-line 30 mm. The largest specimen observed shows a height of 78 mm, with length nearly equal, and hinge-line 42 mm. In this specimen the longest diameter is 85 mm, measured from a point on the upper anterior margin to the lower posterior margin.

This species is distinguished by its form and surface markings. The characters of surface distinguish it from L. Priamus and L. macrodontus, though in form it bears some resemblance to the former; and in the ligamental grooves it is similar to the latter.

Pterinopecten suborbicularis, in some of the younger specimens, resembles this species in general aspect; but none of that species have shown a broad, ligamental area, and the ears continue to increase with the growth of the shell.

Formation and localities. In shales of the Hamilton group at Monteith's Point, Canandaigua lake, Ontario county; Moscow, Geneseo and York, Livingston county; and in the shale and Encrinal limestone, along Lake Erie shore, Eighteen-Mile creek, Erie county, N. Y.

Lyriopecten interradiatus.

PLATE II, FIGS. 1-4; AND PLATE LXXXII, FIG. 5.

Lyriopecten interradiatus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 2, figs. 1-4. Jan., 1883,

Shell large, longitudinally very broadly elliptical; transverse axis somewhat oblique to the hinge-line; height about one-ninth less than the length; margins full and regularly rounded.

Valves about equal in dimensions. Left valve depressed, moderately convex. Right valve tlat, or slightly concave below, becoming convex towards the beak.

Hinge-line straight, central to the body of the shell; length less than twothirds the longitudinal diameter of the shell.

Beak of left valve obtuse, not prominent, directed forward, situated about one-third the length of the hinge-line from the extremity of the anterior ear. In the right valve the umbo is often flat, and the angle subtended by its sides is acute, caused by the deep byssal sinus.

Posterior ears narrow-triangular, distinguished from the gradually sloping sides of the umbo by their flatness and finer markings; margins concave; extremities mucronate. Anterior ear of the left valve smaller, triangular; margins concave; extremity rectangular. Anterior ear of the right valve convex, triangular, truncated at the extremity; separated from the umbo by a deep angular sulcus, and a broad longitudinal semi-elliptical byssal sinus, which forms an indentation in the lateral outline of the body of the shell.

Test of the left valve marked by about 40 strong rounded rays with

smaller intermediate implanted rays, crossed by fine, regular, elevated sharp lines of growth, which at intervals are raised into lamellæ, and appear in the east as strong transverse ridges crossing the radii. The furrows between the radii are narrower than the rays. The regular alternation of the radiating lines where seen is a very conspicuous feature. The right valve is marked by more numerous and subdued rays, and their alternation is somewhat obscure. The ears show fine radiating lines and stronger and more crowded concentric striæ.

The differences between the right and left valves, are the convexity, the surface markings, and the deep byssal sinus of the right valve.

The characters of the interior are not known.

A medium-sized individual has a height of 47 mm., longitudinal diameter 54 mm., hinge-line 32 mm. A smaller specimen measures in height 35 mm., length 38 mm., hinge-line 24 mm.

The largest specimen (imperfect) shows a height of 74 mm., and a length of 88 mm.

In outline and general aspect this species closely resembles *L. macrodontus* (plate 8, figs. 9, 10), but differs in the obliquity of the beak, wider anterior ears, and more elevated and numerous rays. It differs from *L. magnificus* in its outline, larger anterior ears, longer hinge-line, and finer radii of the ears.

The anterior ears of this species, and also of *L. solox* and *L. polydorus*, are smaller than in the species referred to Aviculopecten.

The specimens mostly preserve both valves in connection. A large specimen (plate 82, fig. 5), occurring in the harder argillaceons sandstone, attains nearly the dimensions of *L. cymbaloa* (plate 24, fig. 8), but differs conspicuously in the more numerous, strong radii, their gentle curvature toward the anterior side, and the smaller area of surface upon the anterior side of the vertical axis of the valve.

Formation and locality. In the shales of the Hamilton group, Fultonham, Schoharie county, N. Y.

LYRIOPECTEN MACRODONTUS.

PLATE IV, FIG. 9; AND PLATE VIII, FIGS. 9, 10,

Lyriopecten macrotontus, Hall. Cat. Palæozoic Fossils. S. A. Miller. Cincinnati. 1877.

" Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 4, fig. 9; pl. 8, figs. 9, 10. Jan., 1883.

Shell large, sub-circular; in some large specimens becoming transversely broadovate, from the posterior extension of the valve; height from one-sixth to one-eighth less than the length; margins regularly rounded, more convex at the posterior lateral margin, and extending in nearly a straight line to the beak.

Left valve depressed, moderately convex. Right valve unknown.

Hinge-line straight, nearly central, varying in length with the age of the shell.

Beak obtuse, rounded, directed slightly toward the anterior, not rising above the hinge.

Anterior ear small, about one-third the length of the posterior, triangular, not well-defined; margin straight or slightly concave; extremity obtuse. Posterior ear large, triangular, defined by the absence of the strong radii, and by a shallow, undefined depression reaching to the beak; margin deeply sinuate; extremity acuminate.

Surface marked by from 30 to 40 broad, rounded radii, with usually smaller intermediate rays, crossed by fine striæ of growth. Some fragments of shell, adhering to the internal mould, have a thickness of one millimeter.

Muscular impression large, sub-circular, concentrically striated, situated posterior to, and below the umbonal region. Cartilage-pit very small, triangular beneath the apex of the beak, not extending to the hinge margin. Ligamental area usually marked by five strong, elevated ridges, which curve ontward at the beak, diverging from, and partially enclosing, the cartilage-pit, and continuing toward the extremities of the ears; the innermost ridges disappear before reaching the extremity of the area.

The largest specimen is 85 mm, high, 98 mm, long, and the hinge-line 50 mm. Another specimen, somewhat different in proportions, is 68 mm, in height, 75 mm, long, with hinge-line of 40 mm.

Compared with *L. magnificus*, this species has greater convexity, less elevated radii, and, in general, a comparatively greater longitudinal diameter. It differs from *L. cymbalon* and *L. tricostatus* in surface ornamentation.

This species, described from only the left valve, is nevertheless so distinctly unlike any others here described that it is readily recognized.

Formation and localities. In the coarse beds of the Hamilton group, at Hamilton, Madison county; and Worcester, Ofsego county, N. Y.

LYRIOPECTEN CYMBALON.

PLATE XXIV, FIG. 8.

Lyriopeeten cymbulon, Hall. Pal. N. Y., vol. v, pt. 5. Plates and Explanations: Pl. 24, fig. 8. Jan., 1883.

Shell large, sub-orbicular, not oblique; height a little less than the longitudinal diameter; pallial margin regularly rounded, upper anterior margin more inflated than the posterior, which is truncated toward the beak.

Left valve regularly convex; the basal margin slightly inflected, giving the valve an undue convexity. Right valve not known.

Hinge-line straight, length a little greater than one-half the longitudinal diameter of the shell, and extending about one-third of its length further to the posterior than to the anterior margin.

Beak obtuse, rounded, straight, central; umbonal region defined by its abrupt antero- and post-cardinal margins, and by its convexity.

Anterior ear very small, narrow-triangular; margin concave; extremity obtuse-angular; byssal notch broad and shallow, not conspicuous. Posterior ear large, triangular, marked by a deep sinus; margin convex; extremity angular; length twice as great as the anterior ear.

Test marked by about twelve very strong, continuous, broad, rounded rays, with from one to six smaller ones of variable strength in each of the tlat interspaces; crossed by fine, sharp, regular, concentric striæ of growth, which are elevated into lamellar ridges at irregular intervals. The ears and a broad adjacent space on the body of the valve are destitute of rays, but show strong striæ and undulations of growth. The direction and character

of the rays (in the specimen figured) have been affected, apparently, by some injury received during the life of the animal, which has also produced a strong varix of growth.

Ligamental area 1.5 mm, wide at the beak, whence it diminishes towards the extremities of the hinge-line, marked by several flat, longitudinal striæ. Cartilage-pit broad-triangular, situated under the apex.

The specimen described is 75 mm. in height, 88 mm. in longitudinal diameter, and hinge-line 46 mm. The distance between the centres of two of the large rays at the basal margin is about 17 mm.

The surface markings resemble *L. tricostatus*, but they are stronger, more rugose, and the rays less numerous; also the shell is not oblique, and the beak is more obtuse and rounded. It differs from *L. macrodontus* and *L. magnificus* in its greater convexity, deeper byssal sinus, larger posterior ear, and by its surface characters. This remarkably large and fine species shows conspicuously the diminished anterior ear, a feature also seen in *L. tricostatus*, which is the reverse of many species of recent Pectenidæ, where the anterior ears are developed beyond the posterior; as in *Janira longicauda* (p'Orbigny), and *Pecten Tranquebaricus* (Gmelin).

This species, although seen in only one valve, is characterized by its peculiar surface markings and outline.

Formation and locality. Hamilton group, from a bowlder found near Elmira, N. Y.

Lyriopecten tricostatus.

PLATE IV, FIG. 11; PLATE VII, FIG. 26; AND PLATE X, FIGS. 6-12.

Agicula tricostata, Vanuxem. Geolog. Surv. N. Y.: Report of Third Dist., p. 179, fig. 1. 1843.

Lyriopeeten tricostatus (Vanuxem), Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 4, fig. 11;
pl. 7, fig. 26; pl. 10, figs. 6-12. Jan., 1883.

Shell large, transversely and more or less obliquely broad-ovate; height usually less than the length, the proportions varying with the age of the shell; young specimens are longitudinally elliptical; mature specimens are more oblique; while some abnormal forms show a difference in the direction

of the transverse diameter of nearly 45°; margins full, rounded anteriorly, extended on the postero-basal side, and thence following a nearly straight line to the beak.

Valves similar in general outline. Right valve flat or slightly concave. Left valve moderately convex.

Hinge-line straight, central, varying from more than one-half the longitudinal diameter in young specimens, to less than one-half in mature examples.

Beak pointed, depressed, directed forward, situated anterior to the middle of the hinge-line, and not extending as far as the margin of the hinge. Umbonal angle 90°.

Anterior ear small, triangular, usually less than half the length of the posterior one; margin rounded; extremity obtuse; byssal sinus broad, rounded, indenting the body of the shell, and shortening the anterior ear. In the right valve the notch is deeper and more angular. Posterior ear large, flat, triangular, marked by a distinct sinus which increases with the age of the shell; margin above the sinus straight, convex or coneave; extremity angular. In young specimens the ears are sub-equal, undefined, and without sinus. In older shells the anterior ear becomes diminished, or appears comparatively smaller; while the posterior ear is increased in size.

Surface ornamented by from 20 to 25 strong, rounded, continuous rays, with broad, flat interspaces which show from three to ten smaller radii; and in well-preserved specimens the entire surface of the shell is marked by fine, regular, sharp, elevated, continuous, concentric lines of growth. In the right valve the finer radiating lines are conspicuous, while the others are obscure and more numerous. The ears do not show the stronger rays, but usually preserve the finer radiating and concentric lines, and are marked by regular, concentric undulations, which are not seen on the body of the valves. The thickness of the test is not known.

The hinge-ligament, in mature specimens, has a width of about 2 mm., and is marked with from four to seven longitudinal, raised lines, or liga-

mental grooves, diverging from the cartilage-pit, and continuing parallel to the hinge-line; cartilage-pit small, triangular, placed beneath the beak.

The largest specimen yet seen, of the left valve, is 80 mm. in height, 88 mm. in length, and the hinge-line 35 mm.; the distance between the strong rays at the basal margin is 11 mm. A specimen of medium size is 62 mm. in height, 72 mm. in length, hinge-line 39 mm. A young individual is 23 mm. in height, 29 mm. in length, and hinge-line 18 mm.

This species somewhat resembles in outline *L. macrodontus*, but differs in the surface markings, and the finer parallel teeth of the ligamental area. It differs from *L. magnificus*, *L. interradiatus*, and *L. cymbalon* in outline; the surface of the latter species is similar, but more rugose. From *L. Priamus* it differs in form and surface markings.

In comparing many specimens a great diversity in form and ornamentation will be observed.

Formation and localities. In the lower and middle Chemung beds at Barker, Broome county; Big Flats, Chemung Narrows, and Elmira, Chemung county; and Franklin, Delaware county, N. Y.

Lyriopecten Polydorus.

PLATE VII, FIG. 25.

Lyriopecten Polyclorus, Hall. Pal. N. Y., vol. v, pt. 1 Plates and Explanations: Pl. 7, fig. 25. Jan., 1883.

Shell of medium size; transversely very broad-obovate; height nearly equalling the longitudinal diameter; pallial margins full, regularly rounded on the posterior side; and the anterior side of the left valve passing in nearly a straight line to the beak.

Left valve depressed, nearly flat. Right valve unknown.

Hinge-line straight, length equal to two-thirds the length of the shell, extending posteriorly nearly as far as the posterior margin of the shell.

Beak pointed, directed forward, central to the body of the shell, and forward of the middle of the hinge-line, rising a little above it. Umbonal angle more than 90°.

Posterior ear narrow-triangular, one-third longer than the anterior, the limits not well-defined, and it appears as an expansion or extension of the posterior side of the umbo; margin concave; extremity mucronate. Anterior ear short-triangular; margin convex; extremity rounded, separated from the umbo by a deep, rounded sulcus, which corresponds to the byssal sinus.

Test ornamented by about 25 irregular, strong, rounded rays, with wider interspaces, marked by two or three smaller lines in each one, and crossed by fine strike of growth. The surface markings extend over the ears.

Interior not observed.

The valve described is 28 mm, high, and of about the same length, and the hinge-line 18 mm. The length of the posterior ear is 11 mm, and of the anterior ear 7 mm.

This species bears some resemblance to *L. solox*, but differs in the flatness of the valve and less gibbous umbo. In surface character it is similar to *L. tricostatus*, but has fewer intermediate strice between the stronger rays, which in that species are more simple and rounded; while in other characteristics they are very unlike.

Formation and locality. In argillo-arenaceous slates of the Chemung group near Cassadaga, Chautauqua county, N. Y.

Lyriopecten magnificus.

PLATE VIII, FIG. 8.

Lyriopecten magnificus, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 8, fig. 8. Jan., 1883.

Shell very large, nearly circular; height a little less than the longitudinal diameter; basal and lateral margins regularly rounded.

Left valve nearly flat; the greatest convexity is in the centre of the umbonal region. Right valve unknown.

Hinge-line short, straight, length less than one-half the transverse diameter

of the valve, extending farther toward the posterior than toward the anterior margin.

Beak obtuse, rounded, central to the body of the shell, depressed, not rising above the hinge-line, nor extending to the hinge-margin; umbonal region moderately convex, not defined laterally.

Anterior ear small, narrow-triangular, not well-defined; extremity very obtuse, rounded; margin slightly concave without a decided byssal sinus. Posterior ear triangular, more than twice the length of the anterior, and defined from the umbonal slope by the absence of the strong radii; extremity acuteangular; margin marked by a broad, rounded sinus.

Test marked by about 40 strong, elevated rays, which are somewhat flattened along their summits; usually alternating with one or two sharp or rounded rays, crossed by very fine, sharp, concentric striæ. The radii gradually diminish in strength towards the ears, where they are represented by elevated, narrow lines.

Ligamental area marked by several longitudinal striæ. Other interior characters not known.

The height of the specimen is 97 mm., length 104 mm., hinge-line 44 mm. Three of the stronger rays occupy a space of 12 mm. at the basal margin.

The specimen described is the impression of the exterior of a left valve; it is quite characteristic and very distinct from other known species in its form and surface markings.

In ornamentation and general outline there is some resemblance between this shell and L. macrodontus, but it is less convex, the rays are more elevated, and more sharply defined. The geological horizons of the two species are also widely separated.

Formation and locality. In coarse, arenaceous slates of the Upper Cheming group, at Montrose, Susquehanna county, Penn.

LYRIOPECTEN ANOMLEFORMIS.

PLATE IV, FIG. 10; PLATE X, FIG. 5, AND PLATE LXXXII, FIG. 2.

Lyriopeeten anomiatformis, HALL. MSS, for vol. v. pt. 1. 1877.

Catalogue Amer. Palacozoic Fossils, S. A. Miller. 1877.

Pal. N. Y., vol. v. pt. 1. Plates and Explanations; Pl. 4, fig. 10; pl. 10, fig. 5. Jan., 1883.

Shell larger than medium size, obliquely elliptical or obovate; height nearly equal to the length; the transverse axis makes an angle of about 45° with the hinge-line; margins regularly rounded anteriorly and along the base, becoming obscurely truncated on the upper postero-lateral portion of the shell.

Left valve slightly convex. Right valve nearly flat.

Hinge-line straight, anterior; length equal to one-half the transverse diameter of the shell.

Beak of left valve obtuse, rounded, oblique, not well-defined, situated anterior to the middle of the hinge, and extending to the hinge-margin, but not rising above it. Beak of right valve scarcely defined.

Anterior ear small, obscure, only indicated by the short portion of the ligamental area anterior to the beak. Posterior ear undefined, triangular; margin straight; extremity obtuse. Byssal sinus in the left valve a small notch; in the right valve a very deep, elliptical sinus.

Test thin, marked on the left valve by numerous fine, thread-like radii, of which every fourth to eighth one is much stronger than the intermediate lines, crossed by fine striæ of growth; the larger rays are about 20 in number. On the right valve the radii are represented by obscure, undulating, unequal striæ. The ears show the same surface markings.

Cartilage-pit small. Ligamental area thickened, with about eight flat, longitudinal lines extending to the extremities of the hinge.

A left valve measures 62 mm, from the anterior ear to the postero-basal margin; from the extremity of the beak the height is 55 mm., and the length, parallel to the hinge, is about 54 mm.; hinge-line 27 mm.

The right valve is imperfect, but appears to have been more circular in outline than the left.

This species is characterized by its form, surface ornamentation, and marked resemblance between its right valve and the lower valves of some species of the recent genus Anoma, in the flatness of the valve and deep byssal sinus.

Formation and locality. In the slates of the Chemiung group, at Chemiung Narrows, Chemiung county, N. Y.

Lyriopecten Priamus.

PLATE X, FIGS. 1, 2.

Lyriopecten Priamus, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 10, figs. 1, 2. Jan., 1883.

Shell large, transversely broadly elliptical or ovate, wider below; transverse axis normal or very slightly oblique to the hinge-line; height less than one-tenth greater than the longitudinal diameter; margins regularly rounded.

Left valve moderately and symmetrically convex. Right valve unknown. Hinge-line straight, sub-central; length about one-half the longitudinal diameter of the shell.

Beak obtuse, rounded, oblique, anterior to the transverse axis, not rising above nor extending as far as the hinge-margin.

Anterior ear small and undefined. Posterior ear broad-triangular, flat; margin concave; extremity angular. Byssal sinus not defined.

Test marked by about 40 strong, rounded, irregular radii with narrow interspaces, crossed by fine strike of growth. The rays are often composed of fascicles of thread-like strike, and bifurcate at some point of their length. On the posterior ear the rays are subdued and finer.

Ligamental area 2.5 mm, wide in mature specimens, and marked by numerous sharp, elevated, parallel, longitudinal strice extending to the extremities of the hinge-line. Cartilage-pit triangular, narrow, situated at the apex of the beak, and extending to the margin of the hinge.

One large specimen, which is a east of the interior, measures 72 mm. in height, 70 mm. in length; hinge-line 32 mm. A smaller specimen, showing

the exterior, is 63 mm. in height, 57 mm. in longitudinal diameter, and hinge-line about 31 mm.

In general appearance of surface this shell is similar to L. macrodontus, but the details are quite different.

This species, though characterized from the left valve only, is distinctly different from the others in form and surface ornamentation.

Formation and locality. Associated with numerous segments of crinoidal columns, and rarely with any other fossils, in the upper part of the Cheming group, at Franklin, Delaware county, N. Y.

LYRIOPECTEN FASCIATUS.

PLATE IX, FIGS, 10, 11.

Pernopecten fasciculatus, Hall. MS., vol. v, pt. 1. 1877.

Catalogue Amer. Palæozoic Fossils, MILLER, p. 200. 1877.

Not Avicutopecten fasciculatus, HALL.

Lyriopecten fasciatus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 9, figs. 10, 11.

Jan., 1883,

Shell of medium size, very broadly ovate, erect; length a little less than the width; margins regularly rounded.

Right valve convex, the greatest convexity one-third the width of the valve from the beak. Left valve unknown.

Hinge-line short, straight.

Beak acute, erect, prominent; umbonal region distinctly defined, subtending a right angle.

Anterior ear small, scarcely defined, about half the length of the posterior one. Posterior ear triangular, defined by a well-marked sulcus; margin nearly straight; extremity obtuse. Byssal sinus shallow.

Surface ornamented by strong, low, broad, rounded radii, which increase by interstitial addition; and numerous sharp, elevated, radiating striæ mark the surfaces of the rays, giving them a distinctly fasciculated aspect. These also mark the interspaces, which are narrower than the large rays. Sharp, regular, concentric striæ cancellate the radii. The ears are marked only by the concentric striæ, which are less prominent than on the body of the valve.

Internal characters not known.

The specimen described, is a right valve, having a length of 34 mm., height 36 mm., and hinge-line about 10 mm.

In outline and surface characters this species resembles L. Priamus, but the valve is more convex than the specimen referred to the right valve of that species; it is also less oblique, and the beak more elevated and erect. The rays of L. Priamus are distinctly and frequently bifurcating, while in this species the fasciculate appearance is due to the sharp, elevated striae upon the stronger rays.

Formation and locality. Chemung group, Leon, Cattaraugus county, N. Y.

LYRIOPECTEN SOLOX.

PLATE XXIV, FIG. 5.

Lyriopeeten solox, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 24, fig. 5. Jan., 1883.

SHELL of medium size, nearly circular; transverse axis not inclined to the hingeline; margin regularly rounded, and sloping somewhat abruptly into the byssal sinus.

Right valve moderately convex. Left valve unknown.

Hinge-line straight, length about one-half the diameter of the shell, extending farther on the anterior side.

Beak obtuse, rounded, central, not rising above the hinge-line, directed slightly forward; umbo ample.

Posterior ear triangular, defined by its flattened surface, and the rapid umbonal slope; margin concave; extremity rectangular. Anterior ear imperfect, but showing a very deep and narrow byssal sinus.

Test marked by numerous fine, angular rays, which are arranged in about 40 regular, rounded plications, composed of fascicles of finer rays, with defined interspaces. Finer obscure rays mark the umbo, and the posterior ear shows three or four rounded undulations with lines of growth.

Interior not known, except the ligamental area, which is narrow, and makes an inflection of the hinge-margin of the ears.

The dimensions of the right valve described are as follows: height 43 mm., longitudinal diameter 42 mm., and hinge-line apparently about 25 mm.

This species differs from L. Polydorus by its circular outline, convexity, obtuse beak, ample umbo and surface characters. It differs from L. magnificus and L. macrodontus in the greater convexity of the valve and fullness of the umbo, as well as in the character of the rays. It is also much smaller than those species.

Formation and locality. In a fine semi-calcareous, argillaceous sandstone (lying above the conglomerate?) of the Upper Chemung group, near Panama, Chantauqua county, N. Y.

PTERINOPECTEN, HALL.

PTERINOPECTEN MULTIRADIATUS.

PLATE I, FIGS, 6, 7.

Pterinopecten multiradiatus, Hall. Pal. N. Y., vol. v., pt. 1. Plates and Explanations: Pl. 1, hgs. 6, 7, Jan., 1883.

Shell large, rhomboidal, body of the valve longitudinally obovate; length and height nearly as five to four; anterior and basal margins regularly curved, the postero-basal margin produced and the body of the shell extending thence in a direct line to the beak.

Left valve moderately and regularly convex. Right valve unknown.

Hinge-line straight, anterior, less than the length of the shell.

Beak obtuse, rounded, directed forward, slightly rising above the hinge. Umbonal region ample, subtending an angle of about 105°.

Ears triangular, flat, moderately well-defined; margins slightly concave; extremities rectangular. Posterior ear about twice the size of the anterior, limited by a stronger ray and the abrupt post-cardinal slope of the valve. The anterior ear is limited by a distinct but undefined sulcus. Byssal sinus scarcely marked.

Surface ornamented by numerous strong, distant, clevated, rounded rays, with interspaces marked by a strong ray in the centre, and several finer ones on each side, producing two series of alternations. Concentric strice obscure. The arrangement of the rays gives the surface a fasciculate aspect, especially marked in the impression of the exterior. The rays on the posterior ear are sharp and simple, while on the anterior ear they are similar to those on the body of the shell.

Interior not observed.

The specimen has a length of 48 mm., height 35 mm., hinge-line about 36 mm.

This species is distinguished from P, suborbicularis by its greater length and doubly alternating radii. Though somewhat similar in form to P, crenicostatus, the surface characters are very different.

Formation and locality. In Corniferous limestone at Stafford, Genesee county, N. Y.

Pterinopecten reflexus, n. sp.

PLATE LXXXII, FIG. 8.

Shell of medium size, rhomboidal, moderately oblique; length one-sixth greater than the height; outline regularly curved to the postero-basal margin, thence extending posteriorly.

Left valve depressed-convex; margin reflexed. Right valve unknown.

Hinge-line straight, extended posteriorly, exceeding the greatest length of the shell.

Beak obtuse, low, rounded, directed forward. Umbonal region convex, subtending an obtuse angle.

Posterior ear large, flat, triangular, searcely defined from the umbo; margin slightly convex; extremity obtuse. Anterior ear small, triangular, convex, limited by an undefined sulcus and a shallow byssal sinus; margin nearly straight; extremity obtuse.

Test marked by fine, rounded striæ, alternating with finer lines; intermediate spaces flat. The same surface marking continues in a subdued

degree upon the posterior ear, and somewhat more strongly on the anterior slope and anterior ear.

Internal characters unknown.

The specimen figured has a length, across the middle, of 18 mm., height 15 mm., hinge-line 22.5 mm.

In form, this species resembles P. Hermes, but is distinct in its smaller and less defined anterior ear, less strong radii, and more depressed beak. It is much flatter and of different proportions from P. exfoliates.

Formation and locality. In the Corniferous limestone at the Falls of the Ohio, near Louisville, Ky.

PTERINOPECTEN INSONS.

PLATE I, FIG. 4.

Pterinopecten insons, Hall. Pal. N. Y., vol. v, pt. I. Plates and Explanations: Pl. 1, fig. 4. Jan., 1883.

Shell small, rhomboidal, slightly oblique; length somewhat greater than the height; basal margin regularly rounded; the anterior and posterior sides become nearly vertical as they approach the ears.

Left valve convex, the greatest convexity near the beak. Right valve unknown.

Hinge-line straight, length one-fourth greater than the length of the shell, extended posteriorly.

Beak acute, prominent, anterior to the middle of the hinge, directed forward. Umbonal region prominent, subtending a right angle.

Ears triangular; margins straight; extremities acute. Posterior ear large, undefined. Anterior ear small, convex, with an undefined fold below the cardinal margin, limited by a distinct rounded sulcus. Byssal sinus slightly marked.

Test (in a partially exfoliated specimen) marked by regular, sharp, not numerous rays, with broad, flat interspaces, which, in a perfect condition, have probably been marked by fine striæ. The rays are obsolete over the posterior slope of the valve and the umbo, and also not preserved on either of the ears.

Interior not observed. Ligamental area narrow, appearing as a simple fold of the hinge-margin.

The specimen has a length of 13 mm., height 11 mm., hinge-line 16.5 mm.

In some of the modes of occurrence, this species resembles *P. exfoliatus*, but differs in its proportionally longer hinge-line, more extended posterior ear, comparatively larger anterior ear, and the greatest convexity is nearer the beak.

Formation and locality. Upper Helderberg limestone, Western New York. The particular locality unknown.

Pterinopecten nodosus, n. sp.

PLATE LXXXII, FIG. 13.

Shell small, sub-rhomboidal, slightly oblique; form not fully known.

Left valve very convex.

Beak prominent, nearly erect. Umbonal region very prominent, the limits distinct on the anterior and obscure on the posterior side; subtending an acute angle.

Posterior ear large, triangular; margin very slightly concave; extremity angular. Anterior ear not preserved in the specimen.

Test thin, marked (in a partially exfoliated specimen) by strong, rounded rays with intermediate finer ones, and fine, concentric, undulating, elevated striæ, with numerous concentric undulations, which increase in frequency from the beak to the margin, and on crossing the larger rays, are elevated into strong nodes. On the posterior ear the rays are fine, equal and continuous.

Interior characters unknown.

This species is described from an imperfect specimen of the left valve; but it is so remarkable in its nodose undulations that it is readily distinguished from every other form.

Formation and locality. In the Corniferous limestone at the Falls of the Ohio, near Louisville, Ky.

PTERINOPECTEN EXPOLIATUS.

PLATE I, FIGS. 16, 17; AND PLATE LXXXIII, FIGS. 6, 7,

Pterinopecten exfoliatus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 1, figs. 16, 17, Jan., 1883.

Shell of less than medium size, sub-rhomboidal; body obliquely ovate; length somewhat greater than the height; pallial margins regularly rounded from the anterior ear to the base of the posterior slope, from whence the margin is nearly straight or slightly concave to the extremity of the hinge.

Left valve very convex, inclined to gibbosity. Right valve moderately convex, much smaller than the left.

Hinge-line straight, a little longer than the greatest length of the shell, extended posteriorly.

Beak of left valve prominent, sub-acute, anterior to the middle of, and arching over the hinge-line, directed forward. Umbo prominent, gibbous, the greatest convexity being about the middle of the width, subtending a right angle.

Ears triangular. Posterior ear large, undefined; margin slightly concave; extremity somewhat acute. Anterior ear small, convex, defined by a deep, obtuse sulcus; margin convex; extremity acutely rounded. Byssal sinus distinct, somewhat deep.

Test thin; marked in the left valve by fine, regular, radiating striæ with flat interspaces which show one or two finer rays; crossed by concentric lines of growth and stronger undulations, which in old shells become very prominent. The rays are continued over the ears, and are somewhat subdued and less distinctly alternating on the posterior ears, and obsolete over the upper part of the umbo. The right valve is marked by obsolescent rays and concentric undulations.

Ligamental area narrow.

Three specimens measure respectively as follows: Length 17, 20 and 22 mm., height 15, 18 and 18 mm., length of hinge-line 18, 21 and 23 mm.

In the exfoliated condition, this species resembles *P. insons*; but has a comparatively shorter hinge-line, smaller anterior ear, deeper byssal sinus, and less

extended posterior ear. It is more gibbous and less oblique than P. Hermes, with less conspicuous striæ.

The specimens are usually in the condition of partially exfoliated easts, and retain marks of only the stronger radii and concentric undulations. The differences between the internal mould and the impression of the exterior of the shell are represented in figs. 6, 7, of pl. lxxxiii. This species is not uncommon in the central and western portions of the State.

Formation and localities. In a limestone bed of the Marcellus shale at Avon, Livingston county, Stafford, Genesee county, and Vienna, Ontario county, N. Y.

PTERINOPECTEN DIGNATUS.

PLATE I, FIGS 12, 14, 15.

Pterinopecten dignatus, Hall. Pal. N. Y., vol. v, pt. I. Plates and Explanations: Pl. 1, figs. 12, 14, 15. Jan., 1883.

Shell small, sub-rhomboidal, very slightly oblique; length and height as three to four; pallial margins regularly rounded, somewhat more produced on the postero-lateral portion.

Left valve moderately convex. Right valve depressed, flatter and smaller than the left; it differs in surface markings and depth of byssal notch, and is apparently thinner and more delicate.

Hinge-line straight, length equalling, or greater than, the greatest length of the shell, extending anteriorly beyond the margin of the valve.

Beaks obtuse, rounded, anterior to the centre of the hinge-line, directed slightly forward. Umbonal region ample, subtending an acute angle.

Ears triangular, flat. The posterior ear larger and less distinctly defined than the anterior; margin straight or slightly coneave; extremity rectangular. Anterior ear rounded; margin convex; extremity acute-angular. Byssal sinus moderate in the left valve; deep, narrow and angular in the right valve.

Test of the left valve marked by numerous strong, rounded, increasing radii, with broader interspaces, containing one or two smaller rays which originate about the middle of the valve; crossed by fine, sharply elevated, concentric striæ. The right valve is marked by fine, sub-equal, regular,

radiating striæ, which increase by interstitial addition, and become obsolete on the upper part of the umbo. The radii are also seen on the ears.

Internal characters not observed.

The largest specimen has a length of 19 mm., height 15 mm., hinge-line 19 mm. Another specimen measures 17 mm. in length, 14 mm. in height, with the hinge-line 18.5 mm.

This species closely resembles P. latus, but differs in being less oblique, with greater height, more acute beak, fewer and stronger radii, and a characteristic concentric marking. From P. Hermes it differs in being less oblique, with the posterior ear less extended, and with finer rays upon the ears. From P. conspectus it differs in its greater length, and distinctly different surface markings of the left valve.

Formation and locality. In the Marcellus shale at Bloomfield, Ontario county, N. Y.

PTERINOPECTEN LÆTUS, n. sp.

PLATE I, FIG. 13.

Pterinopecten lautus (in error), Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 1, fig. 13. Jan., 1883.

Shell small, sub-rhomboidal, regularly rounded; length one-sixth less than the height.

Left valve depressed-convex. Right valve unknown.

Hinge-line straight, longer than the greatest length of the valve, extended anteriorly beyond the margin of the shell.

Beak obtuse, anterior to the middle, directed forward, not prominent. Umbonal region scarcely defined, subtending about a right angle.

Ears unequal, triangular. Posterior ear much the larger, undefined; margin very slightly concave; extremity rectangular. Anterior ear smaller, not distinctly defined from the body of the shell; margin above the sinus convex; extremity acute. Byssal sinus moderate.

Entire surface marked by distinct, close, rounded, duplicating radii, crossed by fine, concentric lines of growth. The surface of the umbonal region is

wrinkled from the apex to below the middle of the valve. The surface markings are finer and sub-equal over the posterior ear. A small space on the umbo, as in *Aviculopecten bellus*, is destitute of radii.

Internal characters not known.

This species differs from *P. Hermes* in its less oblique form, shorter hingeline, less ample umbo, and in having no regular alternation in the rays, which are closer and more rounded. It is associated with, and closely allied to, *P. dignatus*, but differs by its more obtuse beak, longer outline, and comparatively more frequent and smaller rays, without the regular concentric striæ.

Formation and locality. In the Marcellus shale at Bloomfield, Ontario county, N. Y.

PTERINOPECTEN HERMES.

PLATE XVII, FIGS, 13-15.

Pterinopecten Hermes, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 17, figs. 13-15, Jan., 1883.

Shell less than medium size, sub-rhomboidal, obliquely sub-ovate; length and height about as three to four; pallial margins regularly rounded, becoming straight on the post-cardinal slope at the junction with the ear.

Left valve moderately convex. Right valve not determined.

Beak acute, prominent, anterior to the middle of the shell directed forward. Umbonal region ample, subtending an angle of about 80°.

Ears very unequal, triangular. Posterior ear much the larger, searcely defined; margin concave; extremity acute. Anterior ear small, slightly convex, defined by a distinct sulcus; margin convex; extremity rounded. Byssal sinus deep.

Test marked by regular, rounded striæ, with wider interspaces which, on the posterior part of the valve, show finer intermediate rays. The ears have essentially the same surface characters as the body of the valve. The entire surface is marked by fine concentric striæ. Umbo with concentric wrinkles. Partial easts of the interior show the same characters as the exterior, but show no muscular or pallial markings. The largest specimen has a length of 19 mm., height 29 mm., hinge-line 29 mm.

This species is very similar in form to *P. lætus*; but the hinge-line is proportionally longer and the radii stronger and more distinctly alternating. It differs from *P. dignatus* in its more oblique form, proportionally greater diameter and sharper radii. From *P. conspectus* it differs in being much more oblique in outline and comparatively narrower.

Formation and locality. In shales of the Hamilton group, Ontario county, N. Y.

PTERINOPECTEN SPONDYLUS.

PLATE XVII, FIG. 16.

Pterinopecten spondytus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations; Pl. 17, fig. 16. Jan., 1883.

Shell small, sub-rhomboidal, scarcely oblique; body of the shell ovate; length somewhat greater than the height; pallial margins regularly rounded, becoming straight on the posterior slope, which is continuous with the margin of the ear.

Left valve convex. Right valve not known.

Hinge-line straight, length greater than the longitudinal diameter of the shell, extended anteriorly.

Beak obtuse, rounded, directed forward, situated anterior to the middle of the hinge-line. Umbonal region prominent, but not strongly defined on the posterior slope; subtending an acute angle.

Ears broad, triangular, flat. Posterior ear much the larger, scarcely defined; margin slightly concave; extremity rectangular. Anterior ear defined by a distinct sulcus; margin convex; extremity rounded. Byssal sinus shallow.

Test marked by regular, sharp elevated rays, with broader interspaces which are marked by finer rays, and concentric foliate lamellæ of growth, which are bent backward in crossing the rays, forming short semi-tubular spines. The radii are less conspicuous on the ears, which also show a few concentric undulations.

Internal characters not preserved. The ligamental area appears as a simple fold in the hinge.

The specimen has a length of 15 mm.; height 13.5 mm.; hinge-line 18 mm.

This species has the general form and aspect of *P. Hermes* and *P. lætus*, but is proportionally wider, with different and characteristic surface markings.

Formation and locality. In soft shales of the upper part of the Hamilton group, shore of Canandaigua lake, Ontario county, N. Y.

PTERINOPECTEN CONSPECTUS.

PLATE XVII, FIGS. 17, 18, 20, 21.

Pterinopecten conspectus, Hall. Pal. N. Y., vol. v., pt. 1. Plates and Explanations: Pl. 17, figs. 17-21.

Jan., 1883.

Shell of medium size, sub-rhomboidal; moderately oblique in young shells, scarcely oblique in older ones; length and height about equal, the length usually a little greater; pallial margins regularly rounded, straighter posteriorly, and merging into the ear without definite limitation.

Left valve moderately convex. Right valve nearly flat, narrower and oblique, with a deeper byssal sinus.

Hinge-line straight, nearly central, equalling, or a little greater than, the length of the shell.

Beak sub-acute, anterior to the centre of the hinge-line, directed slightly forward. Umbonal region somewhat prominent, subtending an angle of about 75°.

Ears triangular. Posterior one much the larger, not distinctly defined on the valve; margin slightly concave; extremity rectangular or somewhat acute. Anterior ear small, distinctly defined by a rounded sulcus; margin convex; extremity rounded or sub-angular. Byssal sinus moderate in the left valve; deep and angular in the right valve, as seen in the specimen figured.

Test of the left valve marked by comparatively few, strong, rounded radii, with intermediate smaller ones, crossed by fine concentric striæ of growth, and strong undulations which interrupt the continuity of the radii. Right valve marked by numerous sub-equal radiating striæ which are somewhat obsolete near the beak, and the umbonal region is marked by some strong concentric wrinkles. The ears present, in a less degree, the same ornamentation as the body of the shell.

Internal characters not observed. Ligamental area simple.

A mature specimen is 27 mm, in length and height, and the hinge-line 28 mm.

This species differs from P. dignatus in being less oblique, the anterior ear less extended, and the radii sharper and more interrupted. It differs from P. latus and P. Hermes in the less obliquity and the stronger surface markings. It differs from P. invalidus, which is similar in general aspect, in being wider, and the margin of the posterior ear less concave.

Formation and localities. In the Hamilton group at Norton's Landing, Cayuga lake, and shores of Skaneateles lake, N. Y.

PTERINOPECTEN FILITEXTUS.

PLATE XVII, FIG. 22; AND PLATE LXXXII, FIGS, 9, 10.

Pterinopecten filitextus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 17, fig. 22.

Jan., 1883.

Shell larger than medium size, transversely semi-elliptical, scarcely oblique; length somewhat greater than the height; margins regularly rounded, less convex on the posterior side.

Left valve moderately convex. Right valve flat or concave.

Hinge-line straight, about as long as the length of the shell, not extended anteriorly beyond the margin.

Beaks obtuse, anterior to the middle of the valve, directed forward, not well defined. Umbonal region not strongly marked.

Ears unequal. Posterior ear wide-triangular, extending as far as the margin of the shell, its limits undefined; margin nearly straight; extremity rectangular. Anterior ear small, limited by a strong sulcus; margin concave; extremity obtuse. Byssal sinus in the left valve moderate; in the right valve well-marked.

Test of right valve thin, marked by fine filiform radii, with much wider interspaces which are marked by finer rays; the same character continuing on the posterior ear, with more equal rays. The entire surface is marked by fine, close, concentric lines of growth, with lamellose elevations at unequal intervals.

Hinge-ligament marked by several parallel grooves.

A right valve measures approximately 35 mm. in length, and 29 mm. in height.

In general form this species resembles *P. conspectus*, but is proportionally longer, and the surface markings are different.

Formation and localities. In the Hamilton group near Cardiff, Onondaga county, and from a bowlder of Hamilton shale at Pine Valley, Chemung county, N. Y.

Pterinopecten intermedius, n. sp.

PLATE XVII, FIG. 19; AND PLATE LXXXIII, FIGS. 4, 5.

Pterinopectea conspectus, in part, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 17, fig. 19, Jan., 1883.

Shell of medium size, sub-rhomboidal, oblique; length one-fourth greater than the height; margins regularly rounded, more convex on the post-basal side.

Left valve convex, greatest convexity below the umbo. Right valve unknown.

Hinge-line straight, somewhat anterior; length greater than the length of the valve.

Beak acute, well defined, arching over the hinge, directed forward, situated anterior to the middle of the shell and of the hinge-line.

Anterior ear small, triangular, with a longitudinal fold; limited by a broad sulcus; margin slightly convex; extremity acute. Posterior ear large, broad-triangular, undefined; margin slightly concave, extending at right angles to the hinge, to the post-basal side of the valve; extremity angular. Byssal sinus broad in the left valve.

Test thin, marked by fine, alternating, filiform, radiating striæ, which increase by implantation until they are very numerous at the basal margins of some specimens, crossed by fine lines of growth with a few concentric undulations. The ears preserve the same surface characters in a subdued degree. Many of the specimens are exfoliated and the surface markings are very obscure or obsolete.

The characters of the interior have not been observed.

A specimen of the left valve has a length of 14 mm., height 12 mm., hingeline 16 mm. A larger example has a length of 19 mm., height 16 mm., and hinge-line 21 mm.

This species was arranged with *P. conspectus*. The recent study and comparison of a more numerous series of specimens shows several important differences, and necessitates the removal of this form from that species.

The present species is more oblique, narrower, and the posterior ear is comparatively longer than in authentic forms of *P. conspectus*.

In *P. Hermes* the hinge-line is more extended posteriorly, and the umbonal angle more obtuse, while in *P. regularis* the hinge is shorter, the extremity of the posterior ear rounded, and the margin continuous with the curvature of the pallial margin of the valve.

Formation and localities. In the shales of the Hamilton group at Ludlowville, Tompkins county, and on the shores of Cayuga and Canandaigua lakes, N. Y.

PTERINOPECTEN REGULARIS, n. sp.

PLATE LXXXIII, FIG. I.

Shell of medium size, semi-circular, body of the valve oblique; length nearly one-fifth greater than the height, greatest length above the middle; margins very full and regularly rounded from the byssal sinus to the posterior extremity of the hinge.

Left valve moderately convex. Right valve unknown.

Hinge line straight, anterior; length a little greater than the length of the valve.

Beak of left valve acute, directed forward, situated anterior to the middle of the hinge.

Anterior ear small, triangular, more than half as long as the posterior ear, limited by a broad sulcus; margin convex; extremity rounded. Posterior ear large and undefined from the body of the valve; margin convex, in regular continuation with the pallial margin; extremity obtuse, angular. Byssal sinus broad.

Test thin, marked with numerous fine, alternating, filiform, elevated strice which are crossed by irregular lines of growth. The ornamentation of the ears is somewhat more subdued than on the body of the valve.

Muscular impression small, ovate, situated below the middle of the posteardinal slope.

A specimen of the left valve has a length of 24 mm., height 19 mm., hinge-line 25 mm. A larger example measures 30 mm. in length.

This species is distinguished for the regular continuous convex curvature of the outline from the byssal sinus to the posterior extremity of the hinge. In this respect it differs from any other form of this genus here described. The right valve of *P. filitextus* has a similar outline, but the left valve has been shown to have the margin of the posterior ear concave and the extremity acute-angular. The specimen of the right valve of that species, figured in

fig. 22 of pl. 17, is imperfect at the posterior extremity of the hinge, and thus resembles the present form more than it would if properly restored.

Formation and localities. In the shales of the Hamilton group, between Geneseo and Avon, and at Delphi, N. Y.

PTERINOPECTEN VERTUMNUS.

PLATE V, FIGS. 1-8; AND PLATE LXXXIII, FIGS. 2, 3.

Pterinopecten Vertumnus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 5, figs. 1-8. Jan., 1883.

Shell large, rhomboidal, oblique; greatest length below the middle of the valve; length about one-fifth greater than the height; margins regularly rounded, becoming full behind and sloping rapidly to the hinge-line.

Left valve depressed-convex. Right valve nearly flat.

Hinge-line straight, somewhat shorter than the length of the shell.

Beaks obtuse, low, anterior to the middle of the hinge-line, directed forward. Umbonal region moderately convex in the left valve, depressed in the right valve, limits defined anteriorly, but not posteriorly.

Ears triangular, flat. Posterior ear much the larger, not defined from the body of the valve; margin gently concave; extremity acute. Anterior ear small, separated from the umbo by an undefined sulcus, and in the right valve by the marked, angular byssal sinus; margin concave; extremity acute, sometimes rounded.

Surface of left valve marked by irregularly alternating, strong, flexuous, flattened radii; interspaces flat; crossed by sharp, elevated, concentric strice which are more closely arranged towards the margin of the shell. The same character of surface continues over the ears, and on the posterior ear the radii are finer, nearly equal in strength, and crenulated by the concentric strice. On the right valve the rays are more equal and finer than on the opposite valve; conspicuous on the posterior ears and subdued on the anterior.

Three specimens have respectively the following dimensions: length 38, 40, 41 mm., height 30, 33, 29 mm., hinge-line 35, 35, 32 mm.

This species resembles *Pterinea reprobus*, from the shales of the Chemung group at Ithaea, which has straighter and more rounded radii in the left valve, with sharper intermediate radii and more elevated, undulating, concentric striæ. The right valve of that species is more convex with stronger and often duplicating radii; while the byssal sinus is less distinctly marked. The present species differs from *Pterinopecten dispandus* in its greater length, proportionally longer hinge-line, less strongly marked right valve, and want of duplication in the radii.

Formation and locality. This species is common in the shales of the Hamilton group at Bear gulf, Schoharie county, N. Y.

PTERINOPECTEN UNDOSUS.

PLATE II, FIGS. 10-19; AND PLATE LXXXII, FIG. 7.

```
Aviculoperten undulatus, Hall. MS. 1877.

"Cat. Amer. Palæozoic Fossils. S. A. Miller. 1877.

Not Pecten undulatus, McCoy. Carb. Foss. of Ireland, p. 101, pl. xvii, fig. 12. 1844.

Not Aviculoperten undulatus, McCoy. 1853.

Pterinoperten undosus. Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 2, figs. 10-19.

Jan., 1883.
```

Shell larger than medium, rhomboidal or sub-orbicular; left valve moderately oblique; right valve scarcely oblique; length one-third greater than the height, proportionally shorter in young shells and in the right valve; anterior and basal margins regularly rounded, somewhat produced behind, and receding rapidly toward the hinge-line.

Valves nearly equally convex; the right valve a little less convex, more orbicular in outline, with deep byssal notch, and different surface markings. When occurring in the softer shales, the valves are often depressed-convex.

Hinge-line straight, length a little less than the height of the shell, nearly central.

Beak obtuse, rounded, scarcely rising above the hinge-line, anterior to the middle of the shell, inclined forward. Umbonal region ample, well-defined, subtending a very obtuse angle.

Ears sub-equal, triangular, undefined; margins concave. Anterior ear limited by a suleus and shallow sinus; extremity acute. In the right valve sub-triangular; margin rounded, defined by an abrupt suleus and a deep, angular byssal notch, which encroaches on the body of the valve. In the posterior ear the extremity is obtuse in the left valve, somewhat more pointed in the right valve.

Test thin, marked by numerous fasciculate rays, which increase by interstitial addition, with interspaces varying from nearly equal to several times the width of the rays; cancellated and sometimes erenulated by elevated, lamellose striæ of growth; and by from three to ten strong, concentric undulations, which are rounded upon the summits. The markings on the ears are similar to those on the body of the shell; the rays on the anterior ear are sometimes obscured by the striæ of growth.

Interior not known. Ligamental area narrow.

A left valve has a length of 51 mm., height 36 mm., hinge-line 36 mm. A right valve has a length of 44 mm., height 37 mm., hinge-line 35 mm. A young specimen has the following dimensions: length 23 mm., height 19 mm., hinge-line 20 mm.

This species is distinctly characterized by the strong, concentric wrinkles, the deep byssal sinus of the right valve, and by the form of the shell. Specimens vary in the frequency and elevation of the radii, and in the number and prominence of the concentric undulations.

The specimens are easts of the interior, with searcely any remaining test. The surface markings are therefore subdued, and the concentric striæ are often not at all preserved.

This species is widely distributed. It has been found in the Corniferous limestone at a single locality; and in the soft shales of the Hamilton group throughout the western portion of the State.

Formations and localities. In the Corniferous limestone at Clarence Hollow, Erie county: in shales of the Hamilton group at numerous localities in Central and Western New York.

Pterinopecten (Aviculopecten?) strictus.

PLATE XXIV, FIG. 2; AND PLATE LXXXI, FIG. 18.

Pterinopecten strictus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations; Pl. 24, fig. 2. Jan., 1883.

SHELL of medium size, transversely semi-elliptical, not oblique; body of the shell ovate, length one-sixth less than the height; anterior and basal margins rounded; posterior margin straight.

Left valve moderately convex. Right valve flat.

Hinge-line straight, equal to the length of the shell, central as regards the transverse axis.

Beaks obtuse, low, directed slightly forward, anterior to the middle of the hinge-line. Umbonal region moderately prominent in the upper part, subtending an acute angle.

Ears triangular. Posterior ear much the larger, flat; margin concave; extremity slightly acute, obscurely defined. Anterior ear small, convex, defined by a well-marked groove or sulcus; margin rounded; extremity acute. Byssal sinus distinct in the left valve, and a deep rounded notch in the right valve.

Test of left valve marked by alternating stronger and finer rounded radii, crossed by sharp, elevated, concentric lines of growth and more distant undulations, with imbricating lamellose lines. These markings are continued over the ears, much subdued on the right valve, and obsolete upon the umbo.

Ligamental area marked by two or three furrows, and a central cartilagepit.

The specimen figured has a length of 25 mm., height 30 mm., hinge-line 25.5 mm.

This species is doubtfully arranged with the present group of forms. In some aspects it resembles *P. conspectus*, but is specifically very distinct. It might be compared with the young of some large forms of Lyriopectex or with Aviculopecten, but the extent of the hinge-line, and the undefined limitation

of the posterior ears, do not assimilate it with the ordinary characters ascribed to those genera.

Formation and locality. In the Chemiung group near Elmira, N. Y.

PTERINOPECTEN IMBECILIS.

PLATE XXIV, FIG. 1.

Pterinopecten imbecilis, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 24, fig. 1. Jan., 1883.

Shell small, rhomboidal, oblique, much longer than high; anterior and basal margins rounded; posterior margin produced.

Left valve moderately convex. Right valve not known.

Hinge-line equal to, or greater than, the length of the body of the shell.

Beak obtuse, directed forward, rather prominent. Umbonal region ample, defined anteriorly; subtending an angle of about 90°.

Ears very unequal, triangular. Anterior ear small, defined by a distinct sulcus. Posterior ear large, undefined; margin concave; extremity angular.

Surface marked by numerous strong, simple radii, with wider interspaces which have usually finer intermediate radii; crossed by fine, equal concentric lines of growth, and stronger, more distant lamellæ, which are elevated and arched backwards over the larger rays, producing nodes.

Internal characters not preserved.

The specimen has a length of 15 mm., height 11 mm., hinge-line about 15 mm.

This species differs from P. lætus, by its distinct and widely separated rays, and more oblique outline.

Formation and locality. In the Chemiung group at Tioga, Tioga county, Pennsylvania.

Pterinopecten dispandus, n. sp.

PLATE LXXXII, FIGS, II, 12.

Shell; length a little greater than the height; margins regularly curved, extending behind.

Left valve convex. Right valve depressed-convex, somewhat smaller than the left, and proportionally longer.

Hinge-line straight, less than the greatest length of the shell, nearly central.

Beaks obtuse, little elevated, anterior to the middle, directed forward. Umbonal region scarcely defined, moderately prominent, subtending a right angle.

Ears triangular, undefined; margins concave. Posterior ear larger than the anterior. Anterior ear limited by an undefined sulcus and moderate sinus; extremity rounded. In the right valve, the anterior ear is narrow, acute, with a deep, angular byssal sinus.

Surface ornamented by prominent, rounded radii, which alternate irregularly with finer intercalated radii, and increase in size and number towards the margin; crossed by concentric striæ, with more distant varices of growth which crenulate the radii. The rays are stronger over the anterior slopes, and are continued on the ears, somewhat finer on the posterior and stronger on the anterior. In the right valve the strong rays are regularly duplicating, and are finer and equal on the posterior ear, with a few stronger ones on the anterior ear.

Ligamental area narrow.

Two left valves measure respectively 45 and 37 mm. in length, 42 and 44 mm. in height, hinge-line 40 and 30 mm. A right valve is 32 mm. in length, 27 mm. in height, hinge-line 28 mm. Other specimens of the left valve vary considerably, apparently according to age.

This species differs from *P. Vertumnus* in its greater proportional height, shorter hinge-line, abruptly rounded radii, and much sharper small intermediate

striæ. The radii upon the right valve are also stronger and distinctly bifureating; the concentric striæ are stronger, closer, and crenulate the rays more distinctly. *P. suborbicularis* is less oblique and the form more rounded, while the rays are more numerous and closely arranged.

Formation and localities. In the Chemiung group at Behnont, Alleghany county, N. Y., and Mansfield, Tioga county, Pennsylvania.

PTERINOPECTEN ERECTUS.

PLATE LXXXII, FIGS 15-17.

Shell above medium size, transversely semi-elliptical, scarcely oblique; length and height nearly equal; pallial margins regularly rounded, slightly extended on the posterior side.

Valves moderately convex. Right valve apparently more convex than the left; the differences between them have not been satisfactorily determined.

Hinge-line straight, length a little greater than the length of the shell.

Beak small, acute, directed forward, little elevated above the hinge-margin; anterior to the middle of the shell. Umbonal region not defined.

Ears triangular, unequal. Posterior ear large, undefined; margin slightly concave; extremity acute. Anterior ear much smaller, not defined; margin concave; extremity acute. Byssal sinus shallow.

Surface marked by numerous rounded unequal radii; the larger ones alternating with one, two or three smaller ones; crossed by fine, sharp, regular, concentric strike of growth. On the ears the strike are fine and uniform.

Interior not known. Ligamental area narrow.

The largest specimen has a length of 32 mm., height 30 mm., hinge-line about 34 mm.

There is some resemblance between this species and *P. dispandus*, but it differs in its comparatively smaller size, longer hinge-line, and somewhat less oblique form.

Formation and locality. In the shales of the Cheming group at a point 600 feet above the base of the formation, at Ithaca, N. Y.

Pterinopecten crenicostatus.

PLATE VIII, FIGS. 3, 4; AND PLATE LXXXII, FIG. 14.

Pterinopecten crenulatus (by error), llall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations; Pl. 8, figs. 3, 4. Jan., 1883.

Shell large, sub-orbicular, slightly oblique; length somewhat greater than the height; pallial margins regularly curved, broadly rounded from the anterolateral to the basal margin; post-lateral margin less convex.

Left valve very moderately convex. Right valve not known.

Hinge-line straight, length one-fifth less than the length of the shell, extended anteriorly, but not as far as the anterior margin of the valve.

Beak obtuse, rounded, searcely directed forward, prominent, anterior to the middle. Umbonal region wide, indistinctly defined on the posterior side, more distinctly limited anteriorly, subtending an angle somewhat greater than 90°.

Ears triangular, flat. Posterior ear five times as large as the anterior, undefined; margin straight or slightly concave; extremity abruptly acute. Anterior ear small; margin deeply concave from the byssal sinus; defined by a distinct sulcus; extremity acute.

Test apparently thick, marked by about fifty strong, rounded rays which are simple or bifurcating, always with finer intermediate rays. Concentric strike strong, elevated, conspicuously crenulating the radii. The radii mark the ears, and on the posterior ear are simple and distant.

Internal characters not known.

The two specimens figured give about the following respective dimensions: length 56, 57 mm., height 47, 53 mm., and length of hinge-line 52 and 46 mm.

This species differs from *P. suborbicularis* in being more inequilateral, with longer hinge, and stronger and less frequent radii. It differs from *P. Neptunus*, pl. 8, fig. 6, by its more erect form, extended hinge-line, distant and elevated radii, with stronger and more elevated concentric striæ.

Formation and localities. In the shales of the Chemung group at Angelica and Conewango, N. Y., and at Mansfield, Tioga county, Pa.

PTERINOPECTEN NEPTUNUS.

PLATE VIII, FIGS. 5-7.

Pterinopecten Neptunus, Hall. Pal. N. Y., vol. v., pt. 1. Plates and Explanations: Pl. 8, figs. 5-7.

Jan., 1883,

Shell large, sub-orbicular, moderately oblique (more so in young shells); length one-fifth greater than the height; pallial margins regularly rounded, becoming extended posteriorly.

Valves moderately and nearly equally convex; very similar in form and surface markings.

Hinge-line straight, length less than the length of the shell, situated anteriorly as regards the body of the valve.

Beaks obtuse, rounded, directed slightly forward, nearly erect, not prominent. Umbonal region wide and undefined posteriorly, subtending a very obtuse angle.

Posterior ear much the larger, slightly concave on the margin; extremity angular. Anterior ear small, separated from the body of the shell by a sulcus; margin convex, extending obliquely outward from the byssal sinus; extremity acute.

Surface marked by closely arranged, rounded or sub-angular rays, which increase by intercalation and bifurcation. The ears are marked by simple and smaller rays, which in the right valve are distinctly angular. The rays become obsolete on the umbo. The concentric strice are close, undulating, and in some conditions may have been sharply elevated and lamellose.

Internal characters not known.

The specimen, fig. 6 of pl. 8 is 55 mm. in length, 46 mm. in height, hingeline 38 mm.

The comparison of this species with *P. crenicostatus* is given under the description of that species.

In surface ornamentation this species somewhat resembles *P. Vertumnus*, but the shell is shorter and less oblique, the hinge-line shorter, and the concentric strice less elevated.

Formation and localities. In the shales of the Chemung group, Angelica and Philipsburg, Alleghany county, N. Y.

PTERINOPECTEN SUBORBICULARIS.

PLATE VIII, FIGS. 1, 2; PLATE XXIV, FIG. 10; AND PLATE LXXXII, FIG. 6.

Pterinea? suborbicularis, Hall. Geolog. Surv. N. Y.: Rep. Fourth Dist., p. 264. 1843.

Pterinopeeten suborbicularis, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 8, figs. 1, 2;
pl. 24, fig. 10. Jan., 1883.

Shell large, rhomboid-orbicular, slightly oblique; length a little greater than the height, or sometimes equal; pallial margins regularly curved, less convex on the posterior side; post-basal margin extended.

Left valve convex. Right valve nearly flat; similar in general form and surface markings.

Hinge-line straight, anterior, nearly equal to the length of the shell.

Beak obtuse, broad, rounded, somewhat depressed, directed slightly forward; a little anterior to the centre of the hinge. Umbonal region expanded, subtending an obtuse angle.

Ears triangular, unequal; extremities angular. Posterior ear the larger, undefined; margin concave. Anterior ear limited by an obscure sulcus. Byssal sinus shallow in the left valve, deep and angular in the right valve.

Surface marked by numerous regular, rounded or sub-angular radii, which increase on the left valve by intercalation, and on the right valve by bifurcation; interspaces nearly equalling the rays. On the posterior ear the rays are finer, and over the body of the shell they are strongly crenulated by lamellose concentric striæ.

Internal characters unknown. The ligamental area is a simple linear groove.

A large specimen measures 63 mm. in length, 55 mm. in height, the hinge-line 55 mm. Another one is 38 mm. in length, 35 mm. in height, with hinge-line 35 mm.

This species is distinguished by its sub-orbicular form, slight obliquity, nearly equal length and height, and comparatively short hinge-line.

The comparison with *P. crenicostatus* is given under the description of that species. It resembles the young of *Lyriopecten orbiculatus*, but the details of the characters are quite different.

Formation and localities. In the Chemung group at Hobbieville and Elm Valley, Alleghany county; New Albion, Cattaraugus county, N. Y., and Mansfield, Tioga county, Pennsylvania.

CRENIPECTEN,* HALL.

CRENIPECTEN AMPLUS.

PLATE IX, FIGS, 9, 13, 18,

Crenipecten amplus, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 9, figs. 9, 13. Jan., 1883. Crenipecten crenulatus? Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 9, fig. 18. Jan., 1883.

Shell larger than medium, broadly and obliquely ovate; height about one-sixth greater than the length; margins regularly rounded, more extended posteriorly.

Left valve very convex. Right valve not known.

Hinge-line straight, about equal to one-half the length of the shell, situated a little anterior to the middle.

Beak obtuse, erect, prominent. Umbonal region very convex, well defined, subtending a right angle.

Ears nearly equal; margins gently concave. Posterior ear somewhat the larger, defined by a sulcus. Anterior ear defined by a sulcus which is more distinct and abrupt. Byssal sinus shallow.

Surface of the cast marked by fine, irregular, concentric striæ, with obsolescent, fine radiating lines. Ligamental area narrow and distinctly crenulate.

^{*}The forms here described under this generic term have in part been referred to Pernopecter by Professor Winchell; but a critical study of the type species of that genus shows that it possesses a large central cartilage-pit with a crenulated hinge-plate on each side below the hinge-margin, which characters alone are sufficient to distinguish the genus and exclude the forms here described under Crenipecten. See discussion of the relations of Pernopecten, Entolium and Crenipecten, in the introduction to this volume.

The largest specimen is 33 mm, in length, 38 mm, in height, hinge-line 16 mm.

This species differs from *P. crenulatus* in its proportionally greater height, rotundity, and less obliquity.

Although known only as a cast, it is distinctively different from other species. Formation and locality. In shales of the Chemung group at Rockville, Alleghany county, N. Y.

CRENIPECTEN CRENULATUS.

PLATE IX, FIGS. 6, 7, 8, 15, 16, 17.

Pecten? crenulatus, Hall. Geolog, Surv. N. Y.; Rep. Fourth Dist., p. 265.—1843.

Crenipecten crenulatus, Hall. Pal. N. Y., vol. v. pt. 1.—Plates and Explanations; Pl. 9, figs. 6-8, 15-17.

Jan., 4883.

Suell of medium size, ovoid-orbicular, moderately oblique; length and height nearly equal: margins regularly rounded, somewhat extended posteriorly.

Right valve convex. Left valve depressed-convex above, and nearly flat below.

Hinge-line straight, length more than one-half the length of the valve, anterior to the middle of the shell.

Beaks obtuse, central, inclined somewhat forward, not rising above the hinge-line. Umbonal region of the right valve prominent, subtending an angle of about 100°.

Ears small, triangular, subequal, limited on the right valve by the rapid slope of the sides of the umbo; margins slightly concave; extremities angular. Byssal sinus not defined.

Test thin; conspicuously marked with fine, concentric striæ of growth, and obscure or nearly obsolete radii (as seen in figs. 7, 8 and 16, pl. 9). The concentric lines are stronger on the ears, and are sometimes cancellated by fine rays.

Ligamental area narrow, crenulated by a row of minute cartilage-pits.

A medium-sized specimen has a length of 29 mm., height 31 mm., hingeline 17 mm. A smaller specimen has a length of 26 mm., height 29 mm., and hinge-line 16 mm.

All the specimens are in the condition of casts or much exfoliated, and the surface markings are therefore obscure.

The species was originally founded upon specimens of the left valve; the right valves shown in figs. 6, 7 and 8, pl. 9, occur in the same association, and have been identified as of the same species.

This species differs from *C. obsoletus* in its proportionally greater convexity and length, and the obliquity of the transverse axis. It is also longer than *C. amplus*.

Formation and locality. In shales of the Chemung group at Rockville, Alleghany county, N. Y.

CRENIPECTEN IMPOLITUS.

PLATE IX, FIG. 14; AND PLATE LXXXIII, FIG. 10.

Crenipecten impolitus, Hall. Pal. N. Y., vol. v., pt. 1. Plates and Explanations: Pl. 9, fig. 14. Jan., 1883.

Shell of medium size, obliquely sub-ovate; length somewhat less than the height; anterior and basal margins regularly rounded, produced behind and extending thence in nearly a direct line to the beak.

Left valve depressed-convex. Right valve not known.

Hinge-line straight, anterior, less than half the length of the shell.

Beak obtuse, rounded, low, inclined a little forward. Umbonal region searcely defined, subtending about a right angle.

Ears nearly equal; margins concave. The posterior ear extends along the posterior margin as a narrow expansion. In well-preserved specimens the ears are defined by sulci. Byssal sinus inconspicuous.

Obscure evidences of concentric striæ appear in the easts.

Internal characters unknown.

Two specimens have respectively the following dimensions: length 24 and 16 mm., width 26, and 19 mm., hinge-line 9 and 7 mm.

In general form and convexity this species resembles *C. crenulatus*, but it is narrower above, with the hinge-line comparatively much shorter.

The specimens are casts of the interior preserved in coarse sandstone; the surface markings are consequently obliterated.

Formation and locality. In a coarse sandstone of the Chemung group near Olean, Alleghany county, N. Y.

CRENIPECTEN OBSOLETUS.

PLATE IX, FIGS, 19, 21.

Lima t obsoleta, Hall. Geolog, Surv. N. Y.: Rep. Fourth Dist., p. 265. 1843 Crenipecten obsoletus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 9, tigs, 19, 21. Jan., 1883.

Shell small, obliquely sub-ovate, length nearly equal to the height; margins regularly curved, becoming produced on the post-basal side, and somewhat rectilinear on the posterior side.

Valves very similar. Right valve depressed-convex. Left valve regularly convex.

Hinge-line straight, a little more than one-half the length of the shell.

Beak obtuse, more prominent on the left valve; situated in the centre of the hinge. Umbonal region well defined in the left valve; depressed and undefined in the right valve.

Ears small, triangular, sub-equal, defined by shallow sulci; margins gently concave; extremities obtuse. Posterior ear a little the larger. Byssal sinus not conspicuous.

Test thin, marked by fine, closely arranged, concentric striæ, which are crowded and stronger on the ears. No radiating striæ have been discovered. Ligamental area narrow, marked by a row of minute cartilage-pits.

A left valve measures 18 mm, in length, 20 mm, in height, hinge-line 10 mm. A similar right valve is 16 mm, in length, 17 mm, in height, hinge-line 8.5 mm.

This species bears some resemblance to *C. crenulatus*, but is more elongate-ovate; less oblique, with the height somewhat greater than length.

Formation and locality. In shales of the Cheming group at Philipsburg, Alleghany county, N. Y.

CRENIPECTEN GLABER.

PLATE IX, FIGS. 20, 22?

Lima glaber, Hall. Geolog. Surv. N. Y.: Rep. Fourth Dist., p. 255. 1843.

Crenipecten glaber, Hall. Pal. N. Y. vol. v. pt. 1. Plates and Explanations: Pl. 9, figs. 20, 22?

Jan., 1883.

Shell small, ovate, erect, very slightly oblique; height about one-fifth greater than the length; pallial margins regularly rounded, more extended on the posterior side.

Left valve moderately convex above, and depressed-convex below. Right valve unknown.

Hinge-line straight, length equal to about one-half the length of the valve. Beak acute, erect, somewhat prominent, not elevated above the hinge.

Umbonal region well defined by the sulei, subtending an acute angle.

Ears triangular, nearly equal, separated from the body of the shell by shallow sulci; margins straight or slightly concave: posterior ear a little the larger. Byssal sinus not distinct.

The east is marked only by fine concentric striæ.

Interior unknown.

The crenulations of the ligamental area are obscure in the specimen.

The original of this species is 12 mm. in length, 16 mm. in height, and hinge-line 6 mm.

This specimen is embedded vertically to the lines of rock bedding, and the proportions of length and height may have been changed. The species is known by its erect form, conspicuous ears and great comparative height.

The specimen of figure 22 is referred with doubt to this species; the erect form is similar; the proportional length is slightly greater.

Formation and localities. In shales of the Chemung group at Philipsburg and Rockville, Alleghany county, N. Y.

Crenipecten Micropterus.

PLATE IX, FIG. 23.

Crenipecten micropterus, Hall. Pal N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 9, figs. 2, 3.
Jan., 1883,

Shell small, longitudinally and obliquely sub-elliptical; length somewhat greater than the height; margins regularly rounded, produced behind and extending in nearly a direct line to the beak.

Right valve depressed-convex. Left valve unknown.

Hinge-line short, straight, anterior; length about one-third the height of the valve.

Beak low, obtuse. Umboual region not strongly defined, subtending an obtuse angle.

Ears very small, nearly equal, bounded by shallow sulci. Byssal sinus not distinct.

Surface marked by numerous low, rounded radii, with wider interspaces and smaller intermediate radii; crossed by fine concentric lines of growth, which are stronger and crowded on the ears, forming their only surface marking.

Interior unknown. Ligamental area obscurely crenulate.

The specimen described has a length of 18 mm., width 16 mm., hingeline 5 mm.

This species resembles in form *C. crenulatus*, but differs in the radii, and in the proportionally much shorter hinge-line. The surface markings are similar to *C. liratus*, but it is different in its proportions of length and height.

Formation and locality. In the shales of the Chemung group at Philipsburg, Alleghany county, N. Y.

CRENIPECTEN LIRATUS.

PLATE IX, FIG. 24; AND PLATE LXXXIII, FIG. 9.

Crenipecten livatus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 9, fig. 24. Jan., 1883.

Shell small, obliquely sub-ovate; length a little less than the height; anterior and basal margins rounded; post-basal margin produced, and thence extending in a direct line to the beak.

Left valve moderately convex, the greatest convexity distant one-third the height of the valve from the beak. Right valve unknown.

Hinge-line straight, short, length about one-third the height of the valve. Beak acute, erect, a little anterior to the centre of the shell, not rising above the hinge. Umbonal region moderately elevated, subtending an acute angle.

Ears small, triangular, defined by moderate sulci; the posterior ear the larger. Byssal sinus not distinct.

Surface marked by prominent, rounded, alternating radii, with intermediate smaller ones. There are about six larger rays, six smaller, and twice that number of still smaller intermediate striæ, all crossed by strong, regular, concentrie laminæ of growth. The ears are apparently destitute of rays.

The crenulations of the ligamental area are small and obscure.

The specimen figured has a length of 20 mm., height 22 mm., hinge-line 7 mm.

This species somewhat resembles C. micropterus in the radii, but differs in all other characters.

Formation and locality. Cheming group at East Randolph, Cattaraugus county, N. Y.

CRENIPECTEN LEON.

PLATE IX, FIG. 12; AND PLATE LXXXIII, FIG. 8.

Creniperten Leon, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 9, fig. 12. Jan., 1883.

Shell of medium size, ovate, slightly oblique; length about one-sixth less than the height; margins regularly curved, produced below, rather straight on the upper part of the posterior side.

Left valve moderately convex; the greatest convexity is a little below the middle.

Hinge-line straight, short, nearly central; length about one-third the height of the valve.

Beak acute, erect. Umbonal region not strongly marked, subtending an acute angle.

Ears sub-equal, small, sulci not conspicuous; posterior ear the larger. A narrow rim, slightly elevated and free from rays, extends from the posterior ear along the margin of the shell.

Surface marked with numerous distinct, rounded or sub-angular rays, and wider interspaces with smaller intermediate rays; with fine concentric striæ and undulations at irregular intervals. The rays are stronger over the posterior half of the valve.

Ligamental area linear, and crenulated with narrow cartilage-pits.

The specimen figured has a length of 26 mm., height 30 mm., hinge-line 10 mm.

This species differs from all the others in its form and surface characters.

Formation and locality. In sandstone of the Chemung group at Leon, Cattaraugus county, N. Y.

CRENIPECTEN WINCHELLI.

PLATE IX, FIGS. 1, 2, 4, 25-30.

Aviculopecten Winchelli, Meek. Pal. of Ohio, vol. ii, p. 296, pl. 15, figs. 50, 56, 1875.

Crenipecten (Pecten) Winchelli (Meek), Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 9, figs. 1, 2, 4, 25-30. Jan., 1883.

Shell larger than medium, flabelliform, equilateral, not oblique; length a little greater than the height; margins regularly rounded below. On the anterior side, from a point two-thirds the height of the valve above the base, the antero-cardinal margin extends in a direct line to the beak; the posterior side, from a point a little above the middle, also slopes in a direct line to the beak.

Left valve moderately convex; the greatest convexity about one-third the height of the shell from the beak. Right valve nearly flat, depressed-convex above. The right and left valves are unlike.

Hinge-line straight, central, length about two-thirds the length of the shell. In several specimens referred to the right valve, the length of the hinge is nearly equal to the length of the valve.

Beak of left valve acute, erect, prominent. Beak of right valve depressed, obtuse, not rising above the hinge-line. Umbonal region of left valve distinctly defined, subtending a right angle.

Ears of left valve triangular, defined by shallow but distinct sulci. Margin of anterior ear convex, with a shallow sinus at the base. Posterior ear the larger; margin concave, with a comparatively broad sinus. The extremities of the ears in the right valve are acute. Byssal sinus deeper and more angular in the right valve.

Surface of left valve marked by numerous rounded or sub-angular, alternating rays, with somewhat wider interspaces, crossed by sharp, elevated, concentric strice; the ears show the same markings. Right valve marked by obscure radii, which are stronger on the ears.

Ligamental area with numerous narrow cartilage-pits.

A large left valve has a length of 47 mm., height 42 mm., hinge-line 29

mm. Another individual measures 27 mm. in length, 26 mm. in height, hinge-line 18 mm. A right valve referred to this species has a length of 20 mm. and a height of 18 mm., hinge-line 17 mm.

This species differs from any known form of Crenipecten; it is like Aviculopecten in external form and surface characters, and resembles the recent genus Pecten.

Mr. Meek compares this species with Aviculopecten Coxanus, Meek and Worthen, from the coal measures of Illinois and Nebraska. It is evident that the crenulations of the hinge have not been previously observed. Except in the hinge crenulations, this form has no other relations with the genus Crenipecten, and it may be found to belong to some genus yet undescribed, which will include other species now placed with the Carboniferous forms of Aviculopecten.

In the original description of the genus, McCoy has not indicated the intimate structure of the hinge, and it is not improbable that there are several generic types among the species included in the Carboniferous forms of Avieulopecten.

The right and left valves have not been found in connection, but their association, and the absence of similar forms in the same beds, render the identity nearly certain.

Formation and locality. In the Waverly sandstone near Newark, Ohio.

PTERINEA, GOLDFUSS.

PTERINEA GRANDIS, n. sp.

PLATE LXXXIII, FIG. 14.

Shell very large, capacious, oblique, sub-rhomboidal, body broadly ovate; length about one-fifth greater than the height; margins regularly rounded, broad along the base, and a little produced on the posterior side.

Left valve convex. Right valve unknown.

Hinge-line straight, apparently somewhat less than the length of the valve, [imperfect in the specimen.]

Beak obtuse, prominent, directed forward. Umbonal region gibbous, subtending an angle of about 90°.

Wing large, triangular, not distinctly defined, margin rounded, with a gentle concavity near the junction of the valve. Ear not observed.

Test thick, marked by distant, strong radii from the umbo to the base; the interspaces having alternating larger and smaller rays; crossed by concentric, undulating lamellose striæ of growth.

Interior unknown.

The specimen has a length of 120 mm., height 100 mm., and the hingeline, from the beak to the extremity of the wing, 95 mm.

This species is distinguished by its large size, very distant strong radii, and convexity. Compared with *P. flabella*, it is proportionally longer, and the wing less defined. Compared with *P. pinguis*, it differs in greater length and somewhat less gibbosity.

Formation and locality. In the upper Helderberg limestone, in Scott Co., Indiana.

PTERINEA PINGUIS.

PLATE XV, FIGS. 2, 3; AND PLATE LXXXIII, FIG. 13.

Pterinea pinguis, Hall. Pal. N. Y. vol. v, pt. 1. Plates and Explanations: Pl. 15, figs. 2, 3. Jan., 1883.

Shell large; gibbons, obliquely ovate, length and height nearly equal. Pallial margins rounded, produced on the posterior basal side, and concave at the junction of the wings.

Left valve ventricose, sub-angular along the anterior side. Right valve unknown.

Hinge-line straight, nearly central; length somewhat greater than the length of the shell.

Beak acute, angular, arching over the hinge, situated near the anterior extremity of the hinge-line, directed forwards. Umbonal region prominent, ventricose, defined, subtending an acute angle.

Wing large, triangular, limited by the rapid post-cardinal slope of the valve; margin slightly concave, rounding to the extremity which is angular. The extent of the ear is not known, but it is limited by a deep sulcus which gives an angular aspect to the antero-cardinal slope of the shell. Byssal sinns not marked in the specimens.

Surface ornamented with about fifteen broad, strong, rounded rays, crossed by lamellæ of growth. The specimens described are weathered casts of the interior and preserve only slight evidence of the surface characters.

Interior not known.

The largest specimen has a convexity of about 20 mm., its length 70 mm., height 65 mm., hinge-line more than 65 mm. Another example has a convexity of about 20 mm., length 63 mm., height 74 mm., hinge-line 55 mm.

This species bears some general resemblance to *P. flabella*; it differs in its large ventricose form, more elevated umbo, the characteristics of the upper part of the anterior side of the body, and the abrupt slope into the wing without a distinct sulcus.

Formation and locality. In the Corniferous limestone, near Columbus, Ohio.

PTERINEA FLABELLA.

PLATE XIV, FIGS. 1-21; PLATE XV, FIGS. 1, 4-6, 8-10; AND PLATE LXXXIII, FIGS. 11, 12

" " (") Sandberger, Verstein, Rhein, Schichtensyst, Nassau, p. 293, pl. 30, fig. 7, 1856.

" costutata, F. A. Roemer, Dunker and von Meyer. Palæontographica, T. 1, fig. 2.

Pterinea flabella, (Conrad) Hall. Pal. N. Y., vol v, pt. 1. Plates and Explanations: Pl. 14, figs. 1-21;
pl. 15, figs. 1, 4-6, 8-10. Jau., 1883.

Shell large; broad or narrow ovate, oblique, rarely erect; length from two-thirds to nearly equal the height; and in some extravagant forms the height is about double the length; the greatest length below the middle; anterior and basal margins regularly curved; the posterior margin from a little above the base, follows a nearly straight line to the beak.

Left valve more or less convex, often gibbous and arcuate. Right valve flat or concave, with a little convexity on the umbo; arcuate, to correspond with the curvature of the opposite valve.

Hinge-line straight, extended upon the posterior side; length greater than the length of the valve.

Beak of left valve acute, rounded, situated near the anterior extremity of the hinge, curving forwards over the hinge margin. In rare instances the beak does not extend quite as far as the margin of the hinge. Umbo of the left valve prominent, gibbous, limited by the sulci of the cardinal expansions, and subtending an angle of from 30° to 60°. Beak of the right valve depressed, rounded, not rising above the hinge; umbonal region depressed-convex, gradually merging into the body of the valve, which is concave below.

Wing large, triangular, nearly flat, varying in proportions, defined (in the left valve) by the post-cardinal slope; margin concave; extremity acute, rounded. Ear of left valve a simple rounded convex lobe or auriculation, defined by a distinct, broad, rounded sulcus; margin rounded above, sinuate at its junction with the valve, forming the byssal sinus. The cardinal expansions of the right valve are similar in dimensions to those of the opposite valve; nearly in the same plane with the body of the shell, and defined only by the surface striæ and the sinus.

Test strong, nacreous, often having a thickness of more than one millimetre. Left valve marked with from six to ten or twelve strong rounded rays, which originate at or near the beak and continue simple to the margin. The interspaces are marked by smaller, alternating costæ, increasing by interstitial addition as the shell increases in size. The surface is also ornamented with strong, elevated, concentric lamellose striæ of growth, which are more or less distinctly bent backwards over the stronger radii. The cardinal expansions are marked with rays; those on the ear in well-preserved specimens, are stronger than on the wing.

In the partially exfoliated condition, and in the casts, the ears show the concentric striæ; and the wings show evidences of the rays. In some conditions the rays are nodose from the concentric laminæ, and in older examples there are undulations of growth which interrupt the rays and increase their nodose aspect.

In the right valve the surface is marked with concentric lines which are more crowded on the cardinal expansions, and with a few strong radii on the wing, which are sometimes quite obsolete.

The casts of the interior sometimes show traces of the stronger radii; but usually they are not preserved.

In the various phases of maceration and exfoliation, the specimens present gradation from the finer radii to the stronger ones, and some specimens are quite destitute of surface markings. They vary also in the number of stronger radii, the development of the wing, the comparative length and width of the body, the arcuation of the valves, the prominence of the beaks, and the thickness of the test. In rare examples, the stronger rays below the umbo are broken up and merged with the finer striæ.

The pallial line originates in a small, deep, anterior muscular impression just beneath the anterior tooth, and extends nearly parallel with the margin of the valve almost two-thirds the distance from the beak to the base of the shell, where it is abruptly recurved, terminating in a large, ovate, posterior muscular impression directly below the posterior extremities of the lateral teeth.

Ligamental area marked by a variable number of sharp narrow grooves, which extend to the extremities of the hinge-line, and probably correspond to the successive laminæ of growth.

In the left valve, there are four or five linear, diverging cardinal teeth, beneath and anterior to the beak; in the right valve only two or three such teeth are seen. Two or three linear, slightly diverging, lateral teeth, are situated below the ligamental area, and posterior to the umbo.

A young symmetrical specimen has a length and height (without the ear) of 15 mm.; and the greatest extent from the beak to the post-basal margin is 21 mm. A medium sized specimen is 36 mm. in vertical height; extreme distance from beak to base 47 mm.; length parallel to hinge-line 35 mm., and hinge-line from beak to extremity of wing 38 mm. Another is 46 mm. in vertical height; extreme distance from beak to base 52 mm.; length parallel to hinge-line 46 mm., and hinge-line from beak to extremity of posterior wing 56 mm. A specimen of different proportions is 52 mm. in vertical height; extreme distance from beak to post-basal margin 63 mm.; length parallel to hinge-line 40 mm.; hinge-line from beak to extremity of posterior wing 40 mm.

This species in surface ornamentation differs greatly from every other form below the Carboniferous period, and possesses true pterinoid characters in a stronger degree than any other species from the New York rocks. The right valve when detached is not so easily distinguished from some other forms, as Pterinea Chemungensis and Actinoptera Boydi.

The species is co-extensive with the Hamilton group throughout the State of New York. An apparently abnormal form, in its unusually large wing, (Pl. XV., fig. 6.) found in the Chemung group, has been referred to this species; and specimens of similar character are common in certain localities.

The specimens occurring in the Chemung group are much larger, and of more extravagant growth, than any yet observed in the Hamilton group. A large specimen has a height of 100 mm.; another measures 90 mm. in length, and is of equal extent along the hinge-line. The costæ on these large forms are often only four in number and very strong and broad. (See plate lxxxiii, fig. 11.)

Formations and localities. This species has been recognized in a single ill-preserved specimen from the Corniferous limestone, at Stafford, Genesee county, N. Y.; casts of the interior, and a single extravagant form preserving the surface characters, have been obtained from limestone of the same age near Columbus, Ohio. It is abundant in the Hamilton group at numerous localities from Schoharie to Cayuga lake, more rarely in the western part of the State; though occurring at Hamburg and elsewhere on Lake Erie shore. It is found in the upper beds of the Chemung group in Steuben county, N. Y., and Tioga county, Pennsylvania.

Pterinea interstrialis, n. sp.

PLATE LXXXIV, FIG 22.

Shell large; left valve obliquely ovate, narrow above; length and height nearly equal; anterior and basal margins regularly curved; posterior margin produced.

Left valve moderately convex, depressed towards base. Right valve unknown.

Hinge-line straight, about equal to the length of the shell.

Beak acute, inclined forward. Umbonal region not prominent, narrow, limited by the cardinal expansions; subtending an acute angle.

Wing triangular, large; margin concave; extremity acute. Ear triangular, small.

Surface marked by about 20 regular, strong, rounded rays which originate on the upper part of the umbo and continue undivided to the margin; with broad, flat interspaces marked by from two to four slender, sharp radii, and crossed by fine concentric striæ. About twelve of the strong rays reach the margin of the valve below the middle of its height, the remainder come out on the upper anterior margin. The wing shows the radii somewhat less strong than the body of the valve. The ear is marked by strong radii.

Interior unknown.

The specimen described has a greatest length of about 55 mm.; height nearly 58 mm.; hinge-line from beak to extremity of wing, about 58 mm.

This species somewhat resembles *P. flabella*; and differs in its less convexity, more numerous strong rays with finer intermediate lines, and less conspicuous concentric striæ.

Formation and locality. In sandstone of the Cheming group at Cheming Narrows, Cheming county, N. Y.

PTERINEA DISPANDA.

PLATE XV, FIG. 7.

Pterinea dispanda, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 15, fig. 7. Jan., 1883.

SHELL large; body very broadly ovate, nearly erect; length greater than the height; anterior margin very convex; basal margin flattened, not produced posteriorly.

Left valve regularly convex, and only moderately gibbous on the umbo. Right valve unknown.

Hinge-line straight, greater than the length of the body, extended posteriorly beyond the margin of the valve.

Beak anterior, nearly rectangular, prominent, directed forward. Umbonal region ample.

Ear small, separated from the body of the shell by a broad undefined sulcus, which is marked by several oblique folds. Byssal sinus deep and abrupt. Wing very large, depressed-convex, broad-triangular; defined by the retral curving of the concentric striæ; concave on the margin; extremity extremely produced and acute.

Test ornamented with strong, unequal, rounded radii, which are sometimes bifurcating on the anterior portion. The wing is marked with similar smaller rays which are sometimes fasciculate. Entire surface also marked by concentric lamellose striæ, which at irregular intervals are crowded into fascicles, giving an undulating aspect to the surface, and a low nodose appearance to the stronger rays.

Interior unknown.

The specimen described has a height of 70 mm., length about 80 mm., and the length of the hinge-line about 90 mm.

This shell bears some resemblance to the more extravagant forms of *Pterinea flabella*, but it is larger than any known specimen of that species, with a proportionally longer and less defined body, and distinctly different surface ornamentation.

Formation and locality. In the upper beds of the Chemung group at Mansfield, Tioga county, Penna.

PTERINEA CHEMUNGENSIS.

PLATE XVI, FIGS. 3, 7, 10, 42; PLATE LXXXIV, FIG. 21.

Aricula Chemungensis, Conrad. John. Acad. Nat. Sci., Phila., vol. 8, p. 243. 1842.

Aricula pecteniformis, Hall. Geolog. Surv. N. Y.: Rept. Fourth Dist., p. 262. 1843.

Pterinea Chemungensis, (Conrad) Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 16, figs. 3, 7, 10, 12. Jan., 1883.

SHELL very large, rhomboidal; body of shell ovate, narrower above, nearly erect, or sometimes oblique; length less than the height; greatest length below the middle; basal and post-basal margins rounded; the anterior margin above the middle is nearly straight, and the corresponding portion of the posterior margin is gently coneave.

Left valve moderately convex above, depressed-convex in the lower part. Right valve depressed-convex towards the beak, flat or slightly concave below.

Hinge-line straight, central; length nearly or quite equal to the length of the shell.

Beak anterior, acute, directed forward, arching a little over the hinge-line. Umbonal region not strongly defined, most prominent a little below the hinge; subtending an acute angle.

Ear short, nearly equilateral, limited by a rounded sulcus; margin concave, with a marked sinuosity and arching of the shell for the byssal sinus. Wing large, triangular, and extending beyond the posterior margin of the valve, not distinctly defined by a sulcus or by marked change in the surface characters from the body of the shell; margin straight or slightly concave; extremity obtuse. In the right valve, the wing is less distinctly defined than in the left.

Test somewhat thin: left valve marked by slender, filiform rays, variously

alternating and bifurcating, or sometimes simple from the umbo to the base, continuing over the wing, and somewhat stronger on the anterior cardinal extremity than on the posterior; the interspaces flat, much wider than the rays. The surface is crossed by fine, closely arranged, concentric striæ, which are occasionally crowded, giving an unequal elevation to the rays. These are also often interrupted and undulated, either from accident to the shell or intermittent growth, and are sometimes nearly obsolete at the base. The right valve is marked by the same interrupted rays on the wing; on the body of the shell the radii are obsolete, but the concentric striæ are preserved. The specimens are generally found as casts, or in an extremely macerated condition.

Ligamental area wide, marked by fine, narrow grooves the whole length of the hinge. Obscure indications of lateral teeth have been seen.

A left valve is 62 mm. in length, 76 mm. in height, hinge-line 55 mm. Another one has a length of 55 mm., height and hinge-line each 62 mm. A very large specimen is 85 mm. in height, 102 mm. from beak to post-basal margin, length 70 mm., hinge-line about 65 mm. A right valve has a length of 55 mm., height 60 mm., hinge-line about 60 mm.

The form varies from nearly erect to considerably oblique, and is usually characterized by the broadly rounded base and interrupted rays, which are coarse and fine, and irregularly arranged.

•This species resembles *P. rigida*, but the radii have an appearance of less rigidity, the hinge-area is narrower and the shell is more oblique. It is closely allied to *P. consimilis*, differing in the proportionally shorter hinge-line, greater height of body, and less obliquity.

Formation and locality. In the Chemung group at Chemung Narrows, Chemung county, N. Y.

PTERINEA CONSIMILIS.

PLATE XVI, FIGS. 1, 2, 8, 9, 11; AND PLATE LXXXIV, FIG. 23,

Pterinea consimilis, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 15, figs. 1, 2, 8, 9, 11. Jan., 1883.

Shell large, sub-rhomboidal, nearly orbicular; length greater than the height; margins regularly curved, moderately produced on the posterior end.

Left valve convex above, depressed-convex below. Right valve convex on the umbo, flat or slightly concave below.

Hinge-line straight, length equal to or a little greater than the length of the valve.

Beak acute, anterior, inclined slightly forward, not rising above the hinge. Umbonal region prominent but not strongly limited, subtending more than a right angle.

Ear small, limited by the abrupt slope of the umbo, which becomes a distinct sulcus in the right valve; margin convex (except in the byssal sinus); extremity rounded. Byssal sinus not distinct. Wing broad, triangular, undefined, much extended; margin concave; extremity acute.

Surface of left valve marked by numerous flattened, slender, filiform rays, with broad, flat interspaces, which are marked by one or two, more or less distinct, finer rays. The radii are often undulating, and become obscure towards the base. The cardinal expansions are correspondingly marked. Fine, closely arranged, inconspicuous concentric striæ cross the surface. The wings of both valves are similar in surface characters. The body of the right valve shows the concentric striæ, with obscure indications of rays.

Ligamental area broad, marked by fine parallel grooves the entire length. Lateral teeth two, strong, converging. Cardinal teeth preserved as three short plications under the beak of the left valve. Pallial line simple, originating anterior to the beak, continuing nearly parallel to the margin of the valve, recurving and terminating in a large muscular scar on the post-cardinal slope adjacent to the wing.

A left valve has a length of 52 mm., height 49 mm., hinge-line about 50

mm. A right valve has a length of 46 mm., height 40 mm., hinge-line 48 mm.

This species differs from *P. Chemungensis* in being shorter, proportionally more extended on the hinge-line, with wider ligamental area, more distinct radii, and greatly different proportions of length and breadth, as shown in the right valves.

Formation and localities. In the Chemung group at Buck's quarry and Chemung, Chemung county, and Smithboro, Tioga county, N. Y.

PTERINEA RIGIDA.

PLATE, XVI, FIGS. 5, 6.

Pterinea rigida, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 16, figs. 5, 6. Jan., 1883.

Shell of medium size, sub-rhomboidal, erect; body ovate, narrow above; length somewhat less than the height; margins regularly rounded, slightly extended on the post-basal portion and straight along the posterior side.

Left valve moderately convex above, depressed-convex below. Right valve unknown.

Hinge-line straight; length about equal to the length of the valve.

Beak acute, prominent, directed forward, rising to the hinge-margin. Umbonal region elevated, subtending an acute angle.

Ear small, limited by the moderate byssal sinus and broad sulcus. Wing large, broad-triangular, undefined; margin slightly concave; extremity angular.

Surface marked with about thirty slender, rigid, rounded rays, which are sometimes flat or grooved along the summit, continuous from the upper part of the umbo; with wider flat interspaces which sometimes show a fine intermediate ray coming in below the umbo. The cardinal expansions are marked by rays of the same character. Lines of growth cross the surface.

Interior unknown.

A medium sized specimen has a length of 31 mm., height 34 mm., hinge-

line about 35 mm. A smaller specimen is 26 mm. in length, 25 mm. in height, hinge-line 24 mm.

This species bears a general resemblance to *P. Chemungensis*; it differs in its continuous and comparatively stronger rigid radii. The group of four species, beginning with *P. Chemungensis*, is well marked and have many characters in common; but nevertheless, present differences which warrant their specific separation.

Formation and localities. In the Chemung group, at several localities in Chemung county, N. Y.

PTERINEA PRORA.

PLATE XVI, FIGS. 4, 13, 14.

Plerinea prova, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 16, figs. 4, 13, 14, Jan., 1883.

SHELL of medium size or larger, sub-rhomboidal, oblique; body ovate, narrow above; length one-fourth greater than the height; margins regularly rounded, extended on the post-basal portion and sloping rapidly into the sinus of the wing.

Left valve moderately convex. Right valve depressed-convex above, flat or concave below, apparently smaller than the left.

Hinge-line straight, longer than the length of the valve, and extending beyond both margins.

Beak small, acute, directed forward, situated at about the anterior fifth of the hinge. Umbonal region undefined, not prominent.

Ear about one-fifth the length of the wing, separated from the body of the valve by a shallow undefined sulcus and marked byssal sinus; margin convex; extremity rounded. Wing large, triangular, extended, defined only by the change in the curvature of its margin from that of the body of the valve; margin deeply concave; extremity acute.

Surface of left valve marked with regular, rounded, sub-equal rays, with

flat interspaces which are sometimes marked by intermediate rays; crossed by fine, concentric lines of growth. The cardinal expansions of both valves show the same character of radii as the body of the left valve. The right valve has subdued rays in the lower posterior portion; the upper part shows only the concentric markings in regular lamellae of growth.

Interior unknown.

One specimen is 34 mm, in length, 28 mm, in height, hinge-line 44 mm. Another is 38 mm, in length, 32 mm, in height, hinge-line about 47 mm.

This species has a resemblance to the left valve of *P. avis*; but the left valve of the present species has greater convexity, more extended hinge-line, and a broad, deep sinusity in the margin of the wing.

The large right valve represented in fig. 4, of plate xvi, is referred with doubt to this species on account of its greater size. This specimen shows a large, broad, elliptical muscular impression near the middle of the post-eardinal slope of the valve.

Formation and localities. In the Chemung group at Buck's quarry near Elmira, and Chemung Upper Narrows, Chemung county, N. Y.

The three following species have the right valves convex, and the left valve nearly flat or concave, being the reverse, in this respect, of the preceding species of the group. The hinge-area is narrow and teeth have not been observed, while the surface markings are peculiar and characteristic in the three forms here described. For these reasons I have considered it desirable to distinguish them, for the present, under a sub-generic head.

VERTUMNIA, n. s. g.

Pterinea (Vertumnia) reversa.

PLATE XXIV, FIGS. 6, 12; AND PLATE LXXXIV, FIG. 24.

Pterinea reversa, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 24, figs. 6, 12.

Jan., 1883.

SHELL large, rhomboid-orbicular; body somewhat oblique; length and height nearly equal; margins regularly rounded, a little more extended on the posterior side.

Left valve flat, or slightly concave, except near the umbo. Right valve moderately convex, the greatest convexity about the middle of the height.

Hinge-line straight, length equal to the length of the valve, extending anteriorly beyond the margin.

Beak of left valve depressed, obtuse, undefined, erect. Beak of right valve low, obtuse, inclined forward. Umbo not distinct in either valve.

Ear of the right valve limited by a distinct broad byssal sinus. Wing triangular, undefined.

Surface marked by strong, rounded, simple, continuous radii which originate upon the umbo; with wide, flat interspaces, which, in the right valve, show occasionally a finer ray; crossed by regularly arranged, sharp, concentric striæ, which are conspicuous both on the rays and interspaces. The rays are obscure and distant on the upper part of the cardinal expansions.

A large right valve has a length of 50 mm., height 47 mm., hiuge-line 55 mm.

This species differs from *P. prora* by its lesser obliquity, the indefiniteness of the cardinal expansions, the convexity of the right valve, and the flat or concave character of the left valve.

Formation and locality. In the Cheming group near Elmira, at the Upper Narrows of Cheming river, N. Y., and in Tioga county, Pa.

PTERINEA (VERTUMNIA) AVIS.

PLATE XXIV, FIGS. 9, 11, 13.

Pterinea reversa, var. avis, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 24, figs. 9, 11, 13, Jan., 1883.

Shell of medium to large size, rhomboidal, oblique; body ovate; length greater than the height; margin moderately rounded in front, becoming full on the posterior side.

Left valve depressed-convex above, flat or concave below. Right valve convex; the greatest convexity about the middle of the valve.

Hinge-line straight, length greater than the length of the shell, extended anteriorly beyond the margin of the valve.

Beak low, obtuse, inclined forward, situated on the anterior third of the hinge-line.

Cardinal expansions unequal, triangular, flat; margins concave; extremities mucronate. Ear limited by a broad, shallow sulcus extending from the beak to the rounded byssal sinus. Wing large, undefined.

Surface of both valves marked by about twenty-five strong, rounded, equal rays, reaching from the umbo to the base, with broad, flat interspaces which occasionally show a single fine intermediate ray. The same surface characters extend over both cardinal expansions. The entire surface is marked by fine, regular, sharp, continuous, concentric striæ.

Internal characters unknown.

A left valve, illustrated on plate xxiv, fig. 13, has a length of 44 mm., height 31 mm., hinge-line 49 mm. A large right valve has a height of 45 mm., length 65 mm., and hinge-line about 65 mm.

This species resembles *P. reversa*, but differs in its comparatively greater obliquity, more extended hinge, and proportionally greater length. It differs from *P. prora* in the flatness of the left valve, the strong rays, the sharp elevated striæ, and the convexity of the right valve.

Formation and locality. In the Chemung group at Buck's quarry, near Elmira, Chemung county, N. Y.

Pterinea (Vertumnia) reproba; n. sp.

Shell of medium size, rhomboidal; body oblique; length somewhat greater than the height: pallial margin regularly rounded, becoming produced behind and

extending thence in a nearly direct line to the hinge.

Valves depressed-convex, the right valve the more convex; very similar in form and surface markings.

Hinge-line straight, length greater than the greatest length of the shell, extended anteriorly considerably beyond the margin of the valve.

Beaks obtuse, not prominent, directed forward, anterior to the middle. Umbonal region undefined.

Ear defined by a shallow sulcus; margin concave; extremity acute. Byssal sinus moderate, marked in the right valve by a partial reflexion of the margin. Wing large, triangular and undefined; margin nearly straight below, slightly concave toward the extremity, which is acute.

Surface marked by numerous strong, rounded rays, which alternate on the left valve, and duplicate on the right valve. The interspaces are equal to, or greater than, the radii; the rays are finer on the cardinal expansions, and very obscure on the ear and umbonal region of the right valve. Concentric striæ regular, sharp.

Interior not known.

Ligamental area narrow, and marked by one or two longitudinal furrows. The sharp striæ in their extension over the hinge-margin give the exterior a crenulated appearance.

A left valve has a length of 25 mm., height 22 mm., hinge-line 30 mm. A right valve has a length of 36 mm., height 28 mm., hinge-line 37 mm.

This species differs from *Pterinopecten Vertumnus* by its comparatively longer hinge-line, more extended ear, less distinctly curving, narrower, and more abruptly elevated radii on the left valve; and stronger, not undulating, duplicating radii of the right valve. The form and proportions are similar to

Pterinopecten lætus, but it is a larger and coarser form, with the right valve convex. The geological positions of the two species are quite different. The character of the surface ornamentation distinguishes it from Pterinea prora and Pterinea axis.

Formation and locality. In shales of the Chemung group, 600 feet above the base of the formation, at Ithaea, N. Y.

ACTINOPTERIA, HALL.

ACTINOPTERIA EXIMIA.

PLATE XXV, FIG. 1.

Actinopteria eximia, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 25, fig. 1. Jan., 1883.

SHELL small, rhomboidal; body falciform, very oblique; length more than one-third greater than the height; margin broadly curved along the ventral side and abruptly recurved over the posterior end.

Left valve convex. Right valve unknown.

Hinge-line straight, less than the length of the valve.

Beak acute, directed forward. Umbonal angle about 60°.

Ear short, oblique, limited by a distinct sulcus; margin convex; extremity rounded. Wing imperfectly preserved in the specimen described, apparently joining the body near the middle of the post-cardinal slope, and very strongly defined; margin concave, extending acutely backwards; extremity acute.

Test marked by about twenty strong, elevated slender rays, with regular lamellæ of growth which are extended and bent backwards on crossing the rays, producing strong semi-tubular spines. The cardinal expansions preserve only the lines of growth.

Interior unknown.

The specimen described has a length of 20 mm., and height of 14 mm.

The description is made from the figure given on plate xxv, as the specimen cannot be found at the time of this writing. The characters of form and surface ornamentation are very characteristic, and the species is important as being the

only one of the genus yet found in the Schoharie grit. It differs from A. muricata in its narrower and more oblique body and shorter wing, as measured along the post-eardinal slope.

Formation and locality. In the Schoharie grit, at Schoharie, N. Y.

ACTINOPTERIA MURICATA.

PLATE XVII, FIGS. 1-3.

Avicula muricata, Hall. Geol. Surv. N. Y.: Rep. Fourth Dist., p. 181, 1843.

Pteronites muricatus, Hall. Cat. Am. Pal. Foss.; S. A. Miller, p. 202, 1877.

Actinopteria muricata, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations; Pl. 17, figs. 1-3, Jan., 1883.

Shell small, sub-rhomboidal; body snb-ovate, very oblique; length one-third greater than the height; margin rounded below, turning abruptly backward on the posterior side, and extending in a direct line to the beak.

Left valve convex. Right valve unknown.

Hinge-line straight from the beak to the posterior extremity, sloping downward on the anterior side; entire length greater than that of the body of the shell.

Beak acute, arching over the hinge, inclined forward, situated at the anterior third of the hinge-line. Umbonal region subtending an acute angle.

Ear broad-triangular, separated from the body of the shell by a broad undefined sulcus which is limited by a strong sub-angular fold extending from the beak, and by the deep rounded byssal sinus; margin convex; extremity obtuse. Wing flat, triangular, defined by having more subdued surface rays; margin deeply sinuate; extremity mucronate.

Test thin, marked with from eight to twelve strong, filiform rays, with finer intermediate ones in the broad, flat interspaces. The rays on the wing are somewhat subdued. Surface crossed by fine concentric lines of growth, which, at intervals, are crowded and raised into lamellæ, and on the rays are produced into tubular spines. These spines are seen only in the better preserved specimens, and appear in the easts as elongate elevations upon the rays. The concentric striæ are conspicuous in the anterior sulcus.

Interior unknown.

Ligamental area grooved.

The largest specimen has an entire length of 16 mm., height 10 mm., hinge-line, to the imperfect posterior extremity, 12 mm. A smaller specimen has an entire length of 14 mm., height 9 mm., hinge-line 15 mm. The smallest specimen measures 10 mm. in length of body and hinge-line, and 6 mm. in height.

In form and surface characters this species is quite unlike any other described from these rocks. In some respects it resembles *A. eximia*, fig. 1, pl. xxv; but has more extended wing and less elongate body.

Formation and locality. In the Marcellus shale at Littleville near West Avon, Livingston county, N. Y.

ACTINOPTERIA DORIS, n. sp.

PLATE XVII, FIG. 4.

Actinopteria Leander, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations; Pl. 17, fig. 4. Jan., 1883.

SHELL small, sub-rhomboidal: body obliquely sub-ovate; length a little greater than the height; margins regularly rounded, sloping abruptly from the upper part of the posterior side to the beak.

Left valve depressed-convex. Right valve unknown.

Hinge-line straight, about equal to the length of the shell (imperfect in the specimen described).

Beak depressed, inclined forward, situated at the anterior third of the hinge. Umbonal region not defined, subtending an acute angle.

Ear not observed. Wing large, flat, not distinctly defined; margin coneave; extremity acute.

Test thin, marked by regular, equal, rounded radii, with wider flat interspaces, and sometimes with obscure intermediate rays. The wing shows finer rays, somewhat crowded at its junction with the body. The fine, concentric lines of growth are stronger on the anterior of the valve, giving a cancellate aspect to the surface.

Interior unknown.

Ligamental area with one or two longitudinal grooves.

The specimen has a length of 18 mm., height 16 mm.

Formation and locality. In the Marcellus shale at East Bloomfield, Ontario county, N. Y.

ACTINOPTERIA SUBDECUSSATA.

PLATE XVII, FIGS, 23, 25-27, 29-31; AND PLATE XIX, FIG. 25.

Pteronites subdecassata, Hall. MS., vol. v. 1877.

S. A. Miller in Cat. Am. Pal. Foss., p. 202. 1877.

Actinopteria subdecussata, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 17, figs. 23, 25-27, 29-31; pl. 19, fig. 25. Jan., 1883.

Shell large, sub-rhomboidal, very oblique; body elongate sub-ovate; height about one-third less than the length; margins regularly enrved, becoming more extended on the posterior side.

The left valve, in old specimens, has the umbo convex above, depressed-convex or flat below, while in young specimens the umbo is altogether convex or gibbous. Right valve moderately convex near the umbo, flat or coneave below the middle.

Hinge-line straight, length about one-fifth less than the length of the shell, not extending as far as the posterior margin of the left valve, but extending beyond the posterior margin of the right valve.

Beak acute, directed forward, somewhat prominent, anterior nearly terminal. Umbonal region (in young shells) well marked by the sulci; umbonal angle acute.

Ear very small, separated by a vertical sulcus. Wing large, triangular, defined in young shells by the abrupt convexity of the post-cardinal slope: in old specimens not distinctly defined; margin concave; extremity acute. The wing of the right valve is larger, and extends beyond the margin of the shell.

Test comparatively thin, marked with regular, sub-angular, alternating radii, the stronger ones extending from the summit of the umbo; a second set interca-

lated on the lower part of the umbo, and a third set of smaller rays coming in toward the margin. The first and second series only are shown in young shells. In the right valve the radii are more subdued. The rays extend over the cardinal expansions of both valves in nearly uniform size. Concentric, elevated, regularly rounded strike of growth cross the rays, and cancellate the surface, and at intervals are crowded together, giving it a lamellose aspect.

Interior unknown.

Ligamental area marked by one or two parallel grooves.

A large specimen has a length of 65 mm., height 47 mm., hinge-line 55 mm. A specimen of medium size has a length of 51 mm., height 35 mm., hinge-line 41 mm. A smaller example has a length of 18 mm., height 11 mm., hinge-line 13 mm.

This species is similar in form to A. decussata, but differs in the convexity of the valves and the less strongly decussated character of the ornamentation, the rays being continuous and annulated by the concentric striæ, while in that species the rays are interrupted by strong concentric lamellæ, between which are the finer lines of growth.

This species is also less abundant and more restricted in geographical range. Formation and localities. In the shales of the Hamilton group on the shores of Canandaigua lake, and near Bellona, Yates county, N. Y.

ACTINOPTERIA DECUSSATA.

PLATE XVII, FIGS. 24, 28; PLATE XVIII, FIGS. 1-15; PLATE XX, FIG. 19; AND PLATE LXXXIV, FIG. 4.

Aricula decussata, Hall. Geol. Surv. N. Y.; Rep. Fourth Dist., p. 203. 1843.
Pleronites decussata, Hall. S. A. Miller, Cat. Am. Pal. Foss., p. 202. 1877.
Actinopteria decussata, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations; Pl. 17, figs. 24, 28; pl. 18, figs. 1-15. Jan., 1883.

Shell large, sub-rhomboidal; body sub-ovate, very oblique; length about one-fourth greater than the height; margins regularly curving; the anterior margin sometimes nearly vertical; posterior margin more abruptly rounded.

Valves convex; the right valve less convex and smaller than the left valve. Hinge-line straight, less than the length of the valve.

Beak acute, prominent, inclined forward, close to the anterior end of the shell. Umbonal region prominent, and in the left valve gibbous; subtending an acute angle.

Ear small, separated from the valve by a broad suleus, beyond which it is a mere fold in the shell. Wing large, triangular, flat, extending nearly to the margin of the valve; limited, in the left valve, by a more or less distinct sulcus, and the abrupt bending of the concentric striæ; margin concave; extremity acute. This character of the wing is somewhat less marked in the right valve.

Test thick; the left valve marked with strong, prominent, rounded radii, regularly alternating with finer ones on the posterior half of the valve; crossed at regular intervals by strong concentric lamellæ; the interspaces marked by fine lines of growth. From maceration or exfoliation these surface characters are usually only partially preserved, or nearly obsolete. In certain conditions the rays become nodose where crossed by the lamellæ, and in many examples the concentric striæ interrupt the rays, leaving them alternating above and below the lamellæ. (See pl. xviii, figs. 13, 14.) The surface characters of the body are continued on the wing, while on the ear the concentric striæ are crowded and conspicuous, and the rays obsolete. In the right valve the markings are much subdued, the rays often obsolete, especially on the lower part of the valve, and the concentric lamellæ are simple undulations of the surface.

Ligamental area narrow, linear; marked, apparently, by a single groove. The cast shows a fold corresponding to the sulcus limiting the wing. Pallial line extending from just anterior and below the umbo to the posterior portion of the body and thence recurving, terminating in a small oval muscular impression. No evidences of teeth are seen in the casts or the interior of valves.

A large specimen has a length of 76 mm., height 56 mm., hinge-line 62 mm. A medium sized example has a length of 52 mm., height 43 mm., hinge-line 42 mm.

This form differs from A. subdecussata in the greater and nearly equal eonvexity of the valves, the stronger, rounded rays, and their interruption by the concentric lamellæ.

Formation and localities. In the Hamilton group, at numerous places in Central and Western New York.

ACTINOPTERIA BOYDI.

PLATE XIX, FIGS. 2-24, 26-30; AND PLATE LXXXIV, FIGS. 16, 17,

"pleuroptera, Conrad.—" p. 242, pl. 13, fig. 2.—1842.
```

Shell of medium size, rhomboidal; body ovate, varying in proportions, the longitudinal axis at an angle with the hinge-line of from 45° to 60°; length varying from nearly equal to one-fourth greater than the height; margins regularly rounded below, straight and nearly vertical for a short distance in front; post-basal side extended.

Valves convex, the right valve a little less convex than the left.

Hinge-line straight from the anterior side of the beak to the posterior extremity.

Beak anterior, acute, prominent, inclined forward, rising above the hinge in the left valve. Umbonal region prominent, subtending an acute angle,

Ear short, oblique, limited by a deep but not sharply defined salcus. Wing large, triangular, not distinctly separated from the body of the shell; margin eoncave; extremity acute. In the right valve the ear is somewhat more extended, the salcus not strong, but the byssal sinus is marked; the wing is proportionally larger and usually more acute at the extremity.

Test thick; the left valve, in well-preserved specimens, is marked by numerous strong, simple, sharp rays, which are continuous from the umbo to

the margin, with rarely intercalated finer rays; crossed by regular, sharp, elevated, concentric lamellae which (in good specimens) are produced into subtubular, spiniform extensions upon the rays. Lines of growth are seen between the lamellae. On the wing the rays are more subdued while the concentric lamellae are strong. The ear is marked only by the crowded concentric striae. On the right valve the radii are obsolete on the body and well-marked on the wing, and the lamellose expansions are conspicuous. In some casts they appear as undulating elevated lamellae.

Pallial line extending parallel to the margin of the shell and terminating in a muscular impression on the posterior slope. A small muscular impression is also seen just in front of the beak, and obscure indications of one or two cardinal teeth.

Ligamental area narrow, striated, marked by two or three slender grooves, which are slightly divergent from the hinge-line.

One of the original specimens of A. quadrula (=A. Boydi) has a length of 30 mm., height and hinge-line each 28 mm. A similar specimen has a length of 25 mm., height and hinge-line each 23 mm.

Two large specimens belonging to the group of A. Boydi have the following respective dimensions: length 38, and 40 mm., height 38, and 35 mm., hinge-line 34, and 30 mm.

This species, in older specimens, resembles A. subdecussata, but differs in the character of the rays, in the less obliquity, and the wider body. The left valve somewhat resembles the right valve of Avicula recticulata, Hisinger, but a comparison of the right valves of both species shows them to be different.

The forms here classed under one specific designation were described by Mr. Conrad under different species, viz.: Avicula Boydii, A. quadrula, A. pleuroptera, and probably A. perobliqua.

The species in its various stages of growth and state of preservation presents a great variation in form and surface characters. The usual condition is that of casts of the interior or specimens more or less exfoliated, leaving the surface markings subdued or obsolescent, and in a few specimens only, have the entire characters of the test in either or both valves been observed. The older specimens show

an extension of the shell along the post-basal margin which is marked by concentric striæ and undulations, while the rays become interrupted and obsolete.

After a study and comparison of a very large number of individuals, it has not been found possible to draw any satisfactory line of specific distinction. The figures on plate xix illustrate all the important varieties of form that have been observed.

The specimens illustrated in figures 2, 3, 4 of plate xix, represent the typical form of A. quadrula, Conrad; the figures 9, 10, 11 of the same plate more nearly correspond to the A. Boydii, Conrad. All the right valves show the same degree of convexity and the same surface characters, and vary in form no more than the variations in the left valve. The extreme forms seen in figures 26 and 27 are old shells, showing the irregular growth of the margins, leaving the upper portions of the shell of normal form and surface characters.

The following are Mr. Conrad's descriptions:

"Avicula *Boydii*, pl. 12, fig. 4.—Sub-rhomboidal, compressed, lower valve with numerons radii, disposed to be interrupted by concentric lines, which are fimbriated, or have numerous angular indentations; anterior wing short, sinuous, truncated; posterior wing ample; posterior extremity of the valves acutely rounded."

"Avieula quadrula, pl. 13, fig. 5.—Sub-quadrate; length and width equal, "compressed; lower valve plano-convex, with distant radii of equal size, "crossed by concentric lines; posterior wing rather shorter than the width of "the shell; anterior wing triangular, beneath which the margin is direct before "rounding to the beak."

The unrecognized form is indicated as follows:

"Avicula pleuroptera, pl. 13, fig. 2.—Lower valve sub-ovate, ventricose, with obsolete radii; summit of umbo above the cardinal line; anterior wing very short; the posterior wing produced, rostrated, acute, with an oblique rib or carina on the posterior half, extending to the acutely angulated extremity." The oblique rib or carina mentioned was probably one of the lateral teeth as shown in figure 12, plate xix.

The Avicula angustivostra of Conrad, cited as occurring at Middleville, Schoharie

county, is probably from the Hamilton shales at Fultonham; and the only species from this locality, answering the description given, is A. Boydii, in a condition in which the radii and elevated concentric lamellæ are more conspicuous than in any specimens from Cazenovia, Hamilton, or any other locality in Central New York.

Formation and localities. In the shales of the Hamilton group; abundant at numerous places in the eastern and central portions of the State.

ACTINOPTERIA PEROBLIQUA.

PLATE XIX, FIG. 31; PLATE LXXXIV, FIG. 14.

Avicula perobliqua, Conrad. Jour. Acad. Nat. Sci., Phila., vol. viii, p. 235, pl. 12, fig. 1, 1842, Actinopteria perobliqua, (Conrad) Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 19, fig. 31. Jan., 1883.

SHELL of medium size, sub-rhomboidal; body very oblique, narrow-ovate; length one-third greater than the height; anterior margin truncate or slightly concave; basal margin regularly arched and acutely rounded over the post-basal side.

Valves very convex. Left valve gibbons in the upper part, angular along the post-cardinal slope. Right valve somewhat less convex.

Hinge-line straight, about two-thirds the length of the shell.

Beak anterior, acute, prominent, inclined forward. Umbonal region gibbous, subtending an acute angle.

Ear a small lobe, defined by a distinct sulcus and shallow, elongate, byssal simus. Wing large, triangular, limited by the angular post-cardinal slope of the valves; margin moderately coneave, sloping forward; extremity angular.

Test (as seen in the specimen, which is a partial cast of the interior), marked by irregular concentric striæ, which become fasciculate on the wing; the surface apparently without rays.

Muscular impression large, sub-quadrangular below the middle of the postcardinal slope, from which, the pallial line curving downward below the middle of the valve, extends parallel with the margin to the anterior side of the umbo.

The specimen described has a length of 37 mm., height 24 mm., hingeline 27 mm.

This specimen occurs associated with A. Boydi and other allied forms, and is known by the convexity of the valves, the sub-angular character of the posterior slope of the left valve, the great obliquity, the proportions of length and height, and the absence of radii in the east.

Mr. Conrad's original description of A. perobliqua is as follows:

- "Avicula perobliqua, pl. 12, fig. 1.—Obliquely sub-ovate, with radiating lines "distinct only on the posterior side; dorsal line rectilinear, long and very "oblique; anterior wing short, wide, sinnous, the front margin inclining to a "regular arch; posterior extremity acutely rounded.
 - " Locality Hamilton, Madison county, N. Y.; Upper Silurian shale.
- "A common species, very easily distinguished from others of the genera with which it is associated, by its long, very obliquely ovate outline. Casts of the interior scarcely exhibit any radiation. It is often found with connected valves."

The radii mentioned in this description cannot be recognized in the specimen which preserves only concentric strike on some parts of the surface. Mr. Conrad's description may have included easts of A. Boydi, which show slight traces of radiation, and occur in the same association.

Formation and locality. In the shales of the Hamilton group, Cazenovia, Madison county, N. Y.

Actinopteria pusilla, ii. sp.

PLATE LXXXIV, FIG. 3.

SHELL small, sub-rhomboidal; body ovate, very oblique; length and height nearly equal; margin for a short distance on the anterior side nearly vertical, broadly rounded along the base and produced on the posterior side.

Right valve convex on the umbo, becoming depressed below the middle of the length. Left valve unknown.

Hinge-line straight, less than the length of the shell.

Beak anterior, acute, moderately prominent. Umbonal region scarcely gibbons, subtending an acute angle.

Wing narrow, triangular, elongate, extending nearly to the posterior end of the shell; margin concave; extremity abruptly acute.

Test thin, marked by elevated, sub-imbricating concentric bands, produced by the lamellose character of the striæ. Crossing these bands, on the posterior half of the shell, are interrupted radiating lines, which indicate the presence of radii upon the original surface. The wing is marked in a similar manner by strong bands, which pass over the hinge-margin, and it also shows two or three interrupted radiating lines, like those on the posterior part of the body of the shell.

Interior unknown.

The specimen described has a length of 11 mm., height 12 mm., and hinge-line 10 mm.

This species is allied to A. decussata and A. Boydi, having the wing characteristic of the former; but it is a proportionally shorter form, and the surface markings are quite unlike the right valve of any of the forms at present known.

Formation and locality. In shales of the Hamilton group, on the shores of Canandaigua lake, N. Y.

ACTINOPTERIA PERSTRIALIS.

PLATE XXIII, FIGS, 2, 7; AND PLATE LXXXIV, FIG. 12.

Actinopteria perstrialis, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 23, figs. 2, 7, Jan., 1883.

SHELL small, sub-rhomboidal; body sub-ovate, axis slightly curved and oblique at an angle of about 45° with the hinge; height about three-fourths the length of the body; basal margin broadly rounded; posterior margin abruptly curved.

Left valve regularly convex, moderately gibbous at the umbo. Right valve depressed-convex below, more convex above.

Hinge-line straight, length equal to the length of the body.

Beaks sub-anterior, in the left valve prominent and rising above the hinge; in the right valve the beak extends to the hinge-line. Umbonal region moderately gibbous in the left valve, convex in the right, subtending nearly a right angle.

Ear short, separated from the body by a marked byssal depression; extremity rounded. Wing narrow, triangular, joining the body midway between the beak and the posterior extremity, not distinctly defined; margin concave; extremity produced and acute. The right valve is less distinctly auriculate in front; the anterior extremity acute; the wing is larger and the margin less abruptly concave.

Test thin, marked by fine concentric striæ which are more conspicuous and equidistant on the right valve. The left valve is marked with fine, closely-arranged radii, which are strongest on the upper margin of the wing. The body of the right valve shows only sharp, distant, concentric striæ; the wing is marked by a few rays in the lower part, and by stronger radii along the hinge-line, which are cancellated by the concentric striæ. The auricle is radiated, and cancellated in the same manner.

Interior unknown.

A left valve has a length of 13 mm., height 10 mm., and hinge-line 12 mm. A large right valve has a length of 15 mm., height 12 mm., and hinge-line 15 mm.

This species differs from A. tenuistriata in its more oblique body, comparatively longer hinge-line, and more closely arranged and stronger radii.

Formation and locality. In the lower part of the Chemung group, near Ithaca, N. Y.

Actinopteria tenuistriata, n. sp.

PLATE LXXXIV, FIGS, 5, 6,

Shell small, sub-quadrate; body short-ovate, oblique at an angle of 60° with the hinge; length about one-fifth greater than the height; anterior margin below the sinus nearly vertical, and then making a broad curve along the base; posterior margin broadly curved.

Left valve regularly convex below the middle, gibbous on the umbo. Right valve smaller, nearly equally convex.

Hinge-line straight, a little greater than the height of the valve.

Beaks at about the anterior third of the hinge-line, prominent, obtuse, rising above the hinge. Umbonal region gibbous and ample, subtending nearly a right angle.

Ear small, defined by a distinct sinus and byssal depression, rounded at the extremity. Wing small, triangular, joining the body below the middle of its length, not strongly limited; margin gently concave; extremity acute.

Test thin, marked by fine concentric striæ, and filiform radiations with wider interspaces, which are marked by extremely slender intermediate striæ. On the anterior side the radiating lines are finer, and on the cardinal margin of the wing they are stronger. The right valve is marked only by elevated concentric striæ, and the wing by fine radiations, which become stronger toward the cardinal margin.

One specimen has a length of 16 mm., height 13 mm., and hinge-line 14 mm.

This species is distinguished from A. perstrialis by its erect and more nearly quadrate form, shorter ear, less extended wing with less concave margin, and more distant, finer striæ.

Formation and locality. In the lower part of the Chemung group at Ithaca, N. Y.

ACTINOPTERIA AURICULATA, n. sp.

PLATE LXXXIV, FIG. 15.

Shell small, rhomboidal; body ovate, oblique at an angle of more than 45° with the hinge: length about one-fifth greater than the height: anterior margin rounded to the sinus; base gently curved; posterior margin abruptly recurved.

Left valve regularly convex below, gibbous above. Right valve unknown. Hinge-line straight, greater than the height of the valve.

Beak anterior to the middle of the hinge-line, acute, prominent, arching over the hinge. Umbonal region abruptly gibbons, subtending an acute angle.

Ear large, straight above, limited by an abrupt vertical byssal depression; extremity rounded. Wing small, not strongly defined, joining the body two-thirds of its length below the beak; margin concave; extremity produced.

Test marked by concentric striæ, and about twenty somewhat strong, sharp radii; this ornamentation is also continued on the wing and the ear.

Interior unknown.

The specimen is 10 mm. in length, 6 mm. in height, hinge-line 7 mm.

This species resembles A. perstrialis in form, but differs in the larger ear, abrupt vertical byssal depression, shorter wing and coarser radii.

Formation and locality. In the Chemung group at Lawrenceville, Tioga county, Pa.

ACTINOPTERIA DELTA.

PLATE XXIII, FIG. 3.

Actinopteria delta, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 23, fig. 3. Jan., 1883.

Shell of medium size, rhomboidal; body broad-ovate, oblique at an angle of about 60°; height less than three-fifths the length; anterior margin rounded, curving into a defined sinus; base broadly curved; post-basal side abruptly rounded.

Left valve gibbons above, gently convex below. Right valve unknown. Hinge-line straight, about equal to the height of the valve.

Beak at about the anterior third of the hinge, directed forward, prominent, rising above the cardinal line. Umbonal region gibbous, nearly rectangular.

Ear rounded, defined by a distinct byssal depression which extends forward from the beak. Wing small, joining the body near the posterior extremity, not strongly defined; margin gently concave; extremity produced.

Test marked by fine concentric striæ, and undulating or interrupted filiform radiations, with wider interspaces, which have probably been marked by finer intermediate striæ. The concentric lines are obscure in the cast and appear as a few irregular concentric undulations.

Interior unknown.

The specimen is 23 mm. in length, 15 mm. in height, hinge-line 16 mm.

Formation and locality. In the lower part of the Cheming group at Ithaca, N. Y.

ACTINOPTERIA EPSILON.

PLATE XXIII, FIGS. 4, 8, (5 and 6?).

Actinopteria epsilon, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 23, figs. 4, 8. Jan., 1883.

Shell of medium size, rhomboidal; body ovate, oblique to the axis at an angle of about 60°; height about three-fourths the length; anterior margin rounded into a very abrupt sinus; base broadly enrved; post-basal side abruptly rounded.

Left valve moderately convex. Right valve depressed-convex above, flat or concave below.

Hinge-line straight, length somewhat less than the height of the valve.

Beaks anterior, acute in the left valve; prominent and elevated above the hinge. Umbonal region gibbons, subtending an angle of less than 60°.

Ear short, defined by a deep, abrupt byssal depression. Wing triangular, joining the body below the middle, not strongly defined; margin regularly coneave; extremity acute and produced.

Test thin, in the left valve marked by somewhat distant, elevated, lamellose, concentric striæ, with intermediate finer lines, and by abruptly elevated rounded rays with wider interspaces; these are cancellated by the concentric striæ, which are more conspicuous on the wing. In the right valve the radiating striæ are subdued, and the concentric striæ become more conspicuous.

Interior unknown.

A specimen of the left valve is 21 mm, in length, 16 mm, in height, and hinge-line 14 mm.

This species differs from A. delta by its narrower form and greater obliquity of body.

Formation and locality. In the lower part of the Chemung group at Ithaca, N. Y.

ACTINOPTERIA ZETA.

PLATE XXIII, FIG. 9; AND PLATE LXXXIV, FIGS. 1, 2.

Actinopteria zeta, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 23, fig. 9. Jan., 1883.

Shell large, rhomboid-orbicular; body broadly ovate, nearly erect; height greater than the length; auricular margin rounded into the byssal sinus; below the sinus the margin is nearly vertical and gradually joining the broad basal curvature; posterior end regularly rounded.

Left valve gently convex below, moderately gibbous above. Right valve flat or concave below, depressed-convex above.

Hinge-line straight, much longer than the greatest length of the valve.

Beak in the left valve sub-anterior, elevated, curving over the hinge; in the right valve depressed, not rising above the hinge-line. Umbonal region subtending nearly a right angle.

Ear small, rounded at the extremity, defined by a strongly marked byssal depression. Wing large, joining the body below the middle, not strongly defined: margin deeply concave in the middle; extremity produced into an acute extension.

Surface marked by strong, elevated, regular, distant, lamelliform, concentric

striæ, with intermediate finer lines, and by slender, filiform, undulating, distant rays, which are more crowded on the anterior side, becoming finer and more numerous at the junction of the wing with the body, and a few much stronger ones along the cardinal line. Rays not present on the ear, which is marked only by the crowded concentric striæ. The concentric striæ crenulate the rays and bend backward in the interspaces, producing a beautifully cancellated surface.

The right valve shows two oblique lateral folds or teeth posterior to the beak.

A right valve has a length of 25 mm, parallel to the hinge, height 28 mm, hinge-line about 34 mm. An imperfect left valve has an approximate length of 22 mm, height 24 mm, and hinge-line 33 mm.

This species is distinguished by its erect, orbicular form, great extension of hinge-line, and marked surface characters.

Formation and locality. In the lower part of the Cheming group at Ithaca, N. Y.

Actinopteria eta, n. sp.

PLATE LXXXIV, FIGS. 8-11.

Shell of medium size, rhomboidal: body broad and short-ovate, oblique at an angle of about 45°; length about one-fourth greater than the height; anterior margin below the sinus nearly vertical, curving gradually into the broad base; posterior side regularly rounded.

Left valve regularly convex below, moderately gibbous above. Right valve smaller, depressed-convex below, gently convex above.

Hinge-line straight, length greater than the height of the shell.

Beak in the left valve sub-anterior, prominent, arching over the hinge; in the right valve subdued, searcely rising above the hinge-line. Umbonal region gibbous in the left valve, subtending an acute angle.

Ear, in the left valve rounded at the extremity, slightly oblique, defined by a distinct byssal depression. In the right valve the ear is larger and flat,

strongly limited. Wing comparatively large, extending three-fourths the length of the valve, not strongly defined; margin coneave; extremity produced and acute. In the right valve the wing is larger, extending almost as far as the posterior side of the valve.

Surface of left valve marked by distant, lamellose, concentric striae, and by radiations with wider interspaces, which have sometimes slender intercalated rays. The concentric lamellæ crenulate the radii, and are arched backward in the interspaces, producing a beautifully cancellated surface. The finer concentric striæ between the lamellæ are rarely visible, and the spaces between the rays show, under a lens and in well-preserved examples, extremely fine, crowded radiations. The radii are also seen in the depression limiting the ear, and on the wing they are equal to those on the body of the valve. The right valve is marked by regular, equidistant, concentric lamellæ. The posterior slope and wing show numerons fine radii which are crossed by concentric striæ continued from the lamellæ on the body of the valve.

Interior unknown.

A small specimen is 20 mm, long, 14 mm, high, and hinge-line 16 mm. A larger imperfect example has, approximately, a length of 30 mm, height 22 mm, and hinge-line 24 mm.

In surface characters this species resembles A. zeta, but is distinguished by its greater obliquity and much smaller wing.

Formation and locality. In the lower part of the Chemung group at Ithaca, N. Y.

ACTINOPTERIA THETA, n. sp.

PLATE LXXXIV, FIGS. 18, 19.

Shell large, sub-rhomboidal: body broadly ovate, oblique at an angle of about 55°; length about one-fourth greater than the height: anterior margin, below the ear, nearly vertical, curving into the broad base: posterior end regularly rounded.

Left valve moderately convex, depressed below. Right valve smaller and less convex, nearly flat below.

Hinge-line straight, length nearly equal to the height of the shell.

Beaks sub-anterior, prominent, arching over the hinge-line in the left valve. Umbonal region moderately gibbous in the left valve, subtending an acute angle.

Ear rounded, a little oblique, defined by a nearly vertical depression. In the right valve the ear is flat or concave, limited by the abrupt elevation of the umbo. Wings large, in the left valve extending about three-fourths the length of the body, and in the right valve joining the body at the posterior end, without distinct limitation in either valve; margin moderately concave; extremity slightly produced, angular.

Surface of left valve marked by sharp, elevated, lamellose, concentric striæ, with intermediate finer lines; and by slender, elevated rays, with wider interspaces between the primary rays, which are often occupied with one or two finer lines; the ear and wing are marked in a similar manner. The rays are distinctly crenulated, and the interspaces are cancellated by the concentric lines, which are slightly curved backward. The surface of the right valve is marked by strong, lamellose, concentric striæ, which become less conspicuous on the wing. The posterior slope of the body and the wing of this valve are marked by numerous fine rays.

Interior unknown.

A specimen, with the two valves attached, has approximately a length of 48 mm., height 30 mm., and hinge-line 33 mm.

This species resembles A. eta, but differs in the more extended wing, finer radii of the left valve, with interstitial additions, narrower interspaces, and more numerous concentric lamellae.

Formation and locality. In the shales of the lower part of the Chemung group at Ithaea, N. Y.

· Actinopteria 10ta, n. sp.

PLATE LXXXIV, FIG. 7,

Shell of medium size, rhomboidal; body broadly ovate, oblique at an angle of about 45°; length about one-seventh greater than the height; anterior margin nearly vertical or slightly inclined for a short distance, thence curving into the broad base; posterior end broadly rounded.

Left valve depressed below, regularly convex above, scarcely gibbons. Right valve unknown.

Hinge-line straight, about equal to the length of the shell.

Beak sub-anterior, prominent. Umbo moderately gibbons, subtending an acute angle.

Ear comparatively short, defined by a distinct byssal depression, rounded at the extremity. Wing not strongly limited, extending quite as far as the posterior extremity of the shell; margin somewhat deeply concave in the middle; extremity produced and acute.

Surface marked by concentric lamellose striæ, and fine thread-like rays, which are crenulated and cancellated by the lines of growth both on the body and on the wing.

Interior unknown.

One of the specimens is 30 mm, in length, 22 mm, in height, and hingeline about 30 mm.

This form resembles A. theta, but the body is proportionally shorter, the hinge-line longer, the wing margin more concave and the extremity more produced.

Formation and locality. In the lower part of the Chemung group at Ithaca, N. Y.

ACTINOPTERIA KAPPA, n. sp. '

PLATE LXXXIV, FIG. 13.

Shell of medium size, rhomboidal; body narrowly ovate, oblique at an angle of less than 45°; length one-third greater than the height; anterior margin oblique, rounded into the broadly curved basal margin; posterior end abruptly rounded.

Left valve depressed below, convex from the middle upward. Right valve unknown.

Hinge-line straight, equal to the height of the valve.

Beak sub-anterior, prominent, arching over the hinge-line. Umbonal region moderately gibbous.

Ear short, oblique, rounded anteriorly, defined by a distinct byssal depression. Wing triangular, joining the body nearly two-thirds of the length from the beak; margin oblique, concave; extremity produced, acute.

Test thin, marked by fine, concentric, irregularly fasciculating striæ, giving an undulated appearance to the surface, and by filiform, interrupted and undulating radii, with wider interspaces, which sometimes show fine intercalated rays. The radii upon the wing are prominent and cancellated by the concentric striæ, and are obsolete upon the ear.

Interior unknown.

The specimen has a length of 30 mm., height 20 mm., and hinge-line 20 mm.

This species differs from A. epsilon, in the greater obliquity, longer hinge-line, and more distant radii.

Formation and locality. In the lower member of the Chemung group at Ithaca, N. Y.

PTYCHOPTERIA, HALL.

PTYCHOPTERIA PROTO.

PLATE XXIII, FIGS. 12, 14,

Ptychopteria Proto, Hall. Pal N. V., vol. v, pt. 1. Plates and Explanations: Pl. 23, figs. 12, 14, Jan., 1883,

Shell small, rhomboidal: body narrow-ovate, oblique at an angle of about 35° with the hinge-line: length more than one-third greater than the height; ante-byssal margin sub-truncate, rounding into the broad sinus: base broadly rounded; posterior end somewhat abruptly curved.

Left valve regularly convex below, gibbous in the middle and above. Right valve unknown.

Hinge-line straight, length a little greater than the height of the valve, and nearly equal to two-thirds its length.

Beak at about the anterior third of the hinge, prominent, inclined forward. Umbo abruptly gibbous, subtending an acute angle.

Anterior end large,* rounded, limited by a broad byssal depression directed backward; extremity angular. Wing small, narrow-triangular, extending to near the posterior end of the body; margin scarcely concave; extremity obtuse.

Surface marked by fine, regular, elevated radii, which are less conspicuous on the wing; also by concentric striæ, which are often crowded and lamellose, producing a somewhat undulated character of the surface.

Interior unknown.

A large left valve has a length of 29 mm., height 18 mm., and hinge-line 20 mm. A smaller specimen has a length of 20 mm., height 13 mm., and hinge-line 14 mm.

This species resembles P, sinuosa, but the anterior end is wider; the wing is smaller and not produced at the extremity, and the radii are coarser. These

^{*}In the descriptions of the species of Ptychopteria and Leptodesma, the term anticle or ear is not so applicable to the anterior extension as in Actinopteria and Leiopteria and the term anterior end has been used for that portion of the shell anterior to the byssal sinus.

two species are distinguished from the forms which follow by the large anterior end which is separated from the body by a broad byssal depression.

Formation and locality. In a coarse sandstone, from a bowlder containing the same associated fossils as a sandstone at Portville, Cattarangus Co., N. Y.; probably of the Upper Chemiung group; Smethport, McKean county, Pa.

Ptychopteria sinuosa.

PLATE XXIII, FIG. 13; PLATE LXXXV, FIG. 8

Ptychopteria sinuosa, Hall. Pal. N. Y., vol. v, pt. 2. Plates and Explanations: Pl. 23, fig. 13. Jan., 1883.

Shell of medium size, rhomboidal; body narrow-ovate, oblique at an angle of about 40° with the hinge; length more than one-third greater than the height; ante-byssal margin nearly vertical, curving into the broad sinus; base broadly rounded; posterior margin recurving into the wing.

Left valve convex below, gibbous in the middle and above. Right valve unknown.

Hinge-line straight, length four-fifths the length of the shell.

Beak at about the anterior third of the hinge, acute, directed forward. Umbonal region strongly gibbous, limited by the abrupt depression of the body on the posterior side, and by the byssal depression on the anterior side. Umbonal angle about 30°.

Anterior end large, narrow, rounded, defined by a broad, shallow, nearly vertical byssal depression; extremity angular. Wing narrow-triangular, extending nearly to the posterior extremity of the body; margin nearly vertical, slightly concave; extremity somewhat produced, angular.

Surface marked by fine undulating radii, which are less conspicuous on the wing, and by fine concentric lines of growth, which are crowded into sub-imbricating lamellæ. On the anterior side of the body the rays are cancellated by the elevated concentric striæ.

The ligamental area shows a sharp linear groove extending three-fourths of its length posterior to the beak, and a narrow cardinal tooth anterior to the beak and parallel to the hinge.

A large specimen of the left valve has a length of 31 mm., height 19 mm., and hinge-line 25 mm. A smaller one has a length of 24 mm., height 13 mm., hinge-line 20 mm.

This species has a narrower anterior end than the preceding, a larger and more extended wing, finer and undulating striae.

Formation and localities. In sandstones of the Upper Chemung group, Smethport, McKean county, and at Warren, Warren county, Pa., associated with Spirifera Verneuili.

PTYCHOPTERIA SALAMANCA.

PLATE XXIII, FIGS, 17-20.

Ptychopteria Salamanca, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations; Pl. 23, figs. 17-20, Jan., 1883.

Shell large, rhomboidal: body sub-ovate, oblique at an angle of about 40° with the hinge-line: length more than once and a half the height; ante-byssal margin oblique, rounded below, slightly concave at the sinus, and sloping to the broadly rounded base, thence abruptly recurved and continued almost vertically into the margin of the wing.

Valves convex, gibbous above the middle. The left valve is more gibbous than the right and somewhat larger.

Hinge-line straight, length more than three-fourths the length of the shell. Beaks in front of the anterior third of the cardinal line, directed forward; the left beak prominent, acute, arching over the hinge; the right beak obtuse, depressed, scarcely rising above the hinge-line. Umbonal region gibbous, subtending an acute angle. The umbo and beak of the left valve are much more prominent, and the post-cardinal slope is obtusely sub-angular.

Anterior end comparatively small, triangular, produced into an acute extension. Wing large, triangular: margin gently concave; extremity produced, acute. The fold and sulcus are more conspicuous in the right valve.

Surface marked by fine, regular, undulating and interrupted radii, which are more conspicuous on the wing: crossing these are regular concentric

lines, which are irregularly crowded into sub-imbricating lamellæ. On the anterior end of the valve the radii are cancellated by the concentric striæ.

Interior characters unknown, except a narrow groove along the ligamental area.

A left valve has a length of 41 mm., height 24 mm., hinge-line 32 mm. A similar right valve has a length of 40 mm., height 24 mm., hinge-line 34 mm.

This species varies in different conditions of preservation. The obtusely sub-angular appearance of the posterior slope is often exaggerated by lateral pressure or subdued by vertical pressure. The same is true of the folds of the wing. In some conditions the radiations are continuous, in others they are cancellated. In weathered specimens the striæ are sometimes nearly obsolete, and the concentric lamellae more prominent.

Formation and locality. In the Cheming group, in a sandstone above the conglomerate at Rock City, near Salamança, N. Y.

PTYCHOPTERIA SAO.

PLATE XXIII, FIGS, 16, 23; AND PLATE LXXXV, FIGS. 14-18.

Ptychopteria 8ao, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 23, figs. 16, 23, Jan., 1883.

Shell of medium size, rhomboidal; body narrow, elongate-ovate, oblique at an angle of about 45° with the hinge-line; length one-third greater than the height; ante-byssal margin obliquely sub-truncate, gently curving into the sinus; base broadly rounded; posterior margin extended, abruptly recurved to the wing.

Valves convex; left valve larger and more convex than the right.

Hinge-line straight, longer than the height of the valve.

Beak in front of the anterior third of the cardinal line obtuse, prominent in the left valve and arching over the hinge; less prominent in the right valve, and rising just above the hinge. Umbo gibbous in the left valve, less gibbous in the right, subtending an acute angle. Anterior end short, small, acute, limited by a shallow byssal depression. Wing large, triangular, extending to near the posterior extremity of the body; margin slightly oblique, scarcely coneave; extremity apparently not produced.

Surface marked by fine radii which are more or less interrupted by the variees of the concentric striæ, and are frequently undulating. The concentric striæ are often fasciculate, and in their usual condition give an undulated appearance to the east, but where well-preserved they are angular and somewhat lamellose.

Interior unknown, except a narrow groove along the ligamental area of the hinge.

A left valve of usual dimensions has a length of 30 mm., height 19 mm., hinge-line 23 mm. A similar right valve has a length of 31 mm., height 18 mm., and hinge-line 22 mm.

This species differs from *P. Proto* in its less angular posterior slope and posterior end; the margin of the wing is less oblique to the hinge and the extremity is not produced.

The specimens occurring in a conglomerate or coarse sandstone have been subjected to different degrees of pressure and maceration, and consequently present a great variety of aspect in the surface ornamentation. The furrow and fold limiting the wing are always less conspicuous in the left valve; and in some cases when the shell has suffered pressure these characters are very obscure.

Formation and locality. Abundant in a conglomerate of the Chemung group at Panama, Chautauqua county, N. Y.

PTYCHOPTERIA EUCRATE.

PLATE XXIII, FIG. 24; PLATE LXXXV, FIGS. 27, 28.

Ptychopteria Eucrate, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations; Pl. 23, fig. 24. Jan., 1883.

Shell above the medium size, rhomboidal; body very narrow, elongate-ovate, oblique at an angle of about 30° with the hinge-line; length nearly twice the height; ante-byssal margin oblique, curving into the sinus; the ventral

margin broadly curved; posterior extremity abruptly or sub-angularly recurved.

Left valve convex, gibbous on the umbo and obtusely sub-angular along the post-cardinal slope. Right valve less convex, somewhat smaller than the left.

Hinge-line straight; length about two-thirds the length of the valve.

Beak near the anterior fourth of the length of the hinge, directed forward; beak of left valve prominent, acute, incurved over the hinge-line; beak of right valve obtuse, and not elevated. Umbonal region of the left valve gibbous and angular, of the right valve convex, subtending a very acute angle.

Anterior end small; margin rounded; extremity acute. Byssal depression oblique, directed backward. Wing narrow, triangular, joining the body at the posterior end; margin obliquely truncate, scarcely concave; extremity apparently not produced.

Surface marked by fine radiating striæ, which are more conspicuous on the body of the valve and upon the wing, and are very obscure on the anterior end: these are crossed by fine concentric striæ of growth which, at irregular intervals, are raised into fascicles, usually more conspicuous on the umbo and post-cardinal slope. On the right valve the radii are usually obsolete.

Interior unknown, except the usual linear groove along the hinge-line.

A large left valve has a length of 40 mm., height 20 mm., and hinge-line 28 mm. Another is 38 mm. in length, height 20 mm., and hinge-line 27 mm.

In this species the body is more oblique than in *P. Salamanca*; the angularity of the left valve is in a direct line down the middle of the body; the shell is comparatively narrower; the extremity of the wing is not produced: the byssal depression is more oblique. The want of strice on the anterior end and their obsolescence on the right valve are marked characters. It is proportionally much longer than *P. Sao*, with which it is associated.

Formation and locality. In the lower part of a conglomerate of the Cheming group at Panama, Chautauqua county, N. Y.

PTYCHOPTERIA THETIS, n. sp. PLATE LXXXV, FIGS. 1-4.

Snell of medium size, rhomboidal; body narrow-ovate, oblique at an angle of about 50° to the hinge-line; length one-third greater than the height; ante-byssal margin obliquely sub-truncate, and curving into a very shallow sinus, from which it makes a broad curve to the sub-angular posterior margin, whence it is abruptly recurved.

Left valve convex below, gibbons above, very obtusely sub-angular along the middle.

Hinge-line straight, length a little greater than the height of the valve.

Beak at about the anterior third of the hinge, prominent, arching over the eardinal line and directed forward. Umbonal region gibbons, subtending an acute angle.

Anterior end short, limited by a nearly vertical byssal depression; extremity acute. Wing of medium size, triangular, joining the body of the shell nearly at the posterior extremity; margin truncate, oblique; extremity apparently not extended.

Surface marked by concentric striæ, which are irregularly fasciculate, and have an angular recurvation along the middle of the body. The body and wing are marked by comparatively fine radii, which are sometimes distinctly cancellated by the concentric lines, and are obscure or obsolete on the anterior portion of the shell, which is marked only by the lamellose concentric striæ.

Interior unknown.

A specimen of the left valve of the usual size has a length of 32 mm., height 21 mm., and hinge-line 22 mm.

This species resembles P. Sao, but the angle of the body to the hinge-line is greater, and from the numbo to the posterior end, the valve is sub-angular; the hinge is longer in proportion, and the fold of the wing less conspicuous.

A right valve in the same association has about the same proportions, but the body is narrower and the radii coarser, making the identity doubtful.

Formation and locality. In a conglomerate of the Chemung group at Panama, Chautauqua county, N. Y.

PTYCHOPTERIA FALCATA, n. sp.

PLATE LXXXV, FIGS, 6, 7.

Shell of medium size, rhomboidal, sub-falcate; body narrow-ovate, oblique at an angle of about 45° with the cardinal line; length one-fourth greater than the height; anterior and basal margins broadly rounded; posterior margin abruptly recurved.

Left valve convex, gibbous above, arcuate. Right valve convex on the umbo, depressed-convex below.

Hinge-line straight, greater than the height of the shell.

Beak situated at about the anterior fourth of the cardinal line, prominent and arching over the hinge in the left valve; not elevated in the right valve. Umbo abruptly gibbous in the left valve, subtending an acute angle.

Anterior end limited by a shallow, nearly vertical byssal depression, which inclines backward in some specimens; margin convex; extremity acuminate. Wing triangular, joining the body near the posterior end; margin straight, slightly concave just below the hinge-line; extremity acute.

Surface of both valves marked by fine radiating striæ, which are less conspicuous on the wing and obsolete on the anterior end; and with concentric striæ, which are sometimes strongly lamellose, producing undulations of the surface.

Interior unknown.

A left valve has a length of 28 mm., height 22 mm., hinge line 24 mm. A similar right valve has a length of 28 mm., height 15 mm., and hinge-line 24 mm.

The shell of this species is comparatively longer, the body more oblique, and the wing smaller than in *P. Thetis*.

Formation and locality. In a sandstone and conglomerate of the Upper Cheming group at Alleghany Springs, Warren county, Pa.

Ptychopteria Spio, n. sp.

PLATE LXXXV, FIG. 19.

Shell of medium size, rhomboidal; body elongate-ovate, oblique to the hingeline at an angle of about 30°; length considerably more than one-third greater than the height; ante-byssal margin curving into a shallow sinns; ventral margin broadly rounded; posterior margin abruptly recurved.

Left valve regularly and moderately convex, gibbous on the umbo. Right valve unknown.

Hinge-line straight, greater than the height of the valve.

Beak in front of the anterior third, moderately prominent and searcely rising above the hinge.

Anterior extremity narrowly acute. Wing very obliquely truncate, joining the body near the posterior extremity: the furrow and fold separating it from the body are only moderately developed; extremity not produced.

Test thin, marked by fine undulating radii which are obsolete on the anterior side; also by concentric strice which are prominent and lamellose on the anterior.

Interior unknown.

The specimen described has a length of 35 mm., height 20 mm., hinge-line 24 mm.

This species differs from *P. Eucrate* in its comparatively greater height; it is less gibbous in the left valve, the posterior end not angularly produced, the byssal depression less conspicuous, and the radii finer. It differs from *P. Sao* in its lesser gibbosity, greater obliquity of the wing margin, and the generally subdued characters of the surface markings.

Formation and locality. In a conglomerate of the Chemiung group, Panama, Chautauqua county, N. Y.

Ptychopteria Eudora, n. sp.

PLATE LXXXV, FIG. 9.

Shell of medium size, rhomboidal; body narrow, elongate-ovate, oblique at an angle of about 30° with the hinge-line; length nearly twice the height; ante-byssal margin oblique, curving into the long, shallow sinus; base broadly curved; posterior end acutely recurved.

Left valve gibbous above, convex below. Right valve unknown.

Hinge-line straight, greater than the height of the shell.

Beak a little in front of the anterior third of the hinge directed forward, rising above the cardinal line. Umbo narrow and gibbous, subtending a very acute angle.

Anterior end small, limited by a well-marked and oblique byssal depression; extremity acute. The distance from the byssal sinus to the cardinal margin is one-half the greatest height of the valve. Wing joining the body one-fourth its length above the posterior end; the shallow furrow and fold defining its limits are not strongly marked; margin obliquely truncate; extremity not produced.

Test thin, marked by radii which are very fine and undulating on the body and wing, while they are obsolete on the anterior portion; these are cancellated by fine concentric striæ, which on some portions are fasciculate, and very conspicuous on the anterior end.

Interior unknown.

The specimen described has a length of 36 mm., height 20 mm., and hinge-line about 23 mm.

This species bears considerable resemblance to *P. Eucrate*, but its anterior end is proportionally narrower, and it may also be distinguished by the absence of a continuous angularity along the body, the more abrupt recurving of the post-basal margin, the more oblique truncation of the wing, and the less conspicuous surface markings. It differs from *P. Spio* in its more gibbous umbo and

more elevated beak, narrower anterior end, more abrupt recurving of the posterior margin, and conspicuous byssal sinus.

Formation and locality. In a conglomerate of the Cheming group at Panama, Chautauqua county, N. Y.

PTYCHOPTERIA ALATA.

PLATE XXIII, FIGS. 25, 26 (21, 22?); AND PLATE LXXXV, FIG. 26.

Ptychopteria alata, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 23, tigs. 25, 26 (21, 22?). Jan., 1883.

Shell large, broadly rhomboidal; body sub-cylindrical, oblique at angle of about 45° with the hinge-line; height less than two-thirds the greatest length; anterior margin oblique, sloping into the broad curvature of the base; posterior margin recurved almost rectangularly, slightly acute.

Left valve gibbous and angular along the axis of the body from the nmbo to the post-basal extremity. Right valve less convex, and less angular in character than the left.

Hinge-line straight, about one-sixth less than the greatest length of the valve.

Beak very prominent in the left valve, directed forward; more depressed in the right valve; situated at about the anterior fifth of the cardinal line.

Anterior extremity in the right valve small, triangular, acute. Wing large, triangular, joining the body at the posterior extremity; the limiting furrow is obscure in the left valve, but very marked in the right; margin of wing gently concave, nearly vertical; extremity angular, little produced.

Surface marked by fine radii which (in the specimens seen) are obscure in the left valve and nearly obsolete in the right; and by concentric striæ which are crowded into imbricating ridges.

Some small right valves found in the same association, and referred with doubt to this species, preserve the radii in a much stronger degree.

Interior unknown.

A large right valve has a length of 42 mm., height 26 mm., and hinge-line 35 mm.

This species is distinguished by the great contrast in the convexity of the two valves. The left valve is strongly angular and elevated from the umbo to the posterior extremity; the right valve is conspicuously alate.

Formation and locality. In a coarse sandstone of the Cheming group, near Salamanca, N. Y.

Ptychopteria trigonalis, n. sp.

PLATE LXXXV, FIGS. 34, 35.

Shell small or of medium size, rhomboidal: body sub-cylindrical, oblique at an angle of about 45° with the hinge-line: length one-third greater than the height: anterior margin rounded, gently curving into the broad base, with a faint byssal sinus: posterior margin almost rectangularly recurved.

Left valve convex, gibbous on the umbo, and angular from the umbo to the post-basal extremity. Right valve unknown.

Hinge-line straight, length greater than the height of the valve.

Beak in front of the anterior third of the hinge, obtuse, prominent and incurved. Umbonal region gibbous, subtending an acute angle.

Anterior end short, rounded, indistinctly separated from the body by an obscure byssal sinus. Wing large, triangular, joining the body of the valve near the posterior extremity; the limiting furrow is very distinct in young shells, and obscure in older examples; margin somewhat obliquely truncate; extremity not produced.

Surface marked by fine radii, which are obscure or obsolete on the anterior part of the shell: also by concentric striæ, which are somewhat acutely recurved on the angular portion of the body, and in older shells are fasciculate, producing an undulated aspect.

Interior unknown.

A small left valve has a length of 16 mm., height 11 mm., and hinge-line 13 mm. Another specimen has a length of 30 mm., height 18 mm., and hinge-line 25 mm.

This species has some resemblance to *P. alata* in the left valve, but its height is comparatively greater, the wing more truncate, and not produced at the extremity.

Formation and locality. In a shaly sandstone above a conglomerate in the upper part of the Chemiung group at Panama, Chautauqua county, N. Y.

PTYCHOPTERIA ELONGATA, n. sp.

PLATE LXXXV, FIGS 10-13

Shell of medium size, sub-rhomboidal, elongate; body sub-cylindrical, oblique at an angle of 30° with the hinge-line; length more than one-third greater than the height; anterior margin oblique, curving into the basal margin, with a slight concavity for the byssal sinus; posterior margin abruptly rounded.

Left valve regularly convex below, gibbous above. Right valve somewhat depressed-convex.

Hinge-line straight, about one-fifth less than the length of the valve.

Beaks near the anterior fourth of the hinge, directed forward; left beak prominent, sub-acute, arching over the cardinal line; beak of right valve depressed, obtuse, scarcely rising above the hinge-line. Umbo gibbous in the left valve; the greatest convexity of the valve is about one-third the length from the beak. Umbonal angle acute.

Anterior end short, produced and acute at the extremity, limited by a distinct oblique byssal depression. Wing narrow-triangular, joining the body of the shell near the posterior extremity, limited by a furrow which is not conspicuous in the lower part, but in the right valve is more marked: margin obliquely truncate.

Surface marked by fine radii, which are distinctly cancellated by the concentric striæ, when the specimen is tolerably well-preserved; also by concentric lines of growth which, at somewhat regular intervals, are sharply elevated. The radii are obsolete on the anterior of the valve, and the concentric striæ are lamellose.

The connected valves show a narrow ligamental area extending half the length of the hinge. Other characters of the interior are unknown.

One specimen has a length of 35 mm., height 21 mm., and hinge-line 25 mm. Another has a length of 25 mm., height 13 mm., and hinge-line 20 mm.

This species resembles *P. Eucrate*, but is less gibbons, more elongate, and without angularity along the body.

Formation and locality. In a conglomerate of the Cheming group at Panama, Chautanqua county, N. Y.

PTYCHOPTERIA GALENE, n. sp.

PLATE LXXXV, FIGS, 29-31

SHELL small, rhomboidal; body sub-elliptical, oblique at an angle of about 40° with the bringe; height greater than half the length; ante-byssal margin oblique, curving gently into a shallow sinus; base regularly rounded; posterior end abruptly recurved.

Left valve convex, moderately gibbous on the umbo, and sub-angular along the upper half. Right valve less convex above, depressed-convex in the lower part.

Hinge-line straight, length greater than the height of the valve.

Beaks near the anterior third of the hinge, inclined forward, prominent, arching over the hinge-line. Umbo gibbons, subtending somewhat less than a right angle.

Anterior end small, limited by the shallow, nearly vertical byssal depression; extremity acute. Wing wide-triangular, joining the body near the posterior end; limiting furrow distinct; fold wide and moderately prominent; margin obliquely truncate, very slightly concave just below the hinge-line; extremity angular.

Surface of the body and wing marked by regular, fine, interrupted or undulating radii, which are obscure or obsolete on the anterior portion; also by very fine concentric lines, which are crowded into irregular fascieles and are lamellose on the anterior part of the valve. Interior unknown.

A left valve has a length of 26 mm., height 18 mm., and hinge-line 20 mm. Another specimen has a length of 24 mm., height 14 mm., and hinge-line 17 mm.

Compared with *P. Eucrate* and *P. elongata*, the body of the shell is comparatively shorter, the furrow of the wing more distinct, the byssal depression shallower and more nearly vertical. It has the obscure angularity of *P. Eucrate*, with coarser and more nearly vertical radii.

Formation and locality. In the lower beds of the Upper Division of the Cheming group, as seen at Warren, Pa.

PTYCHOPTERIA BEECHERI, n. sp.

PLATE LXXXV, FIGS. 21, 22.

Shell large, rhomboidal: body cylindrical, very arcuate in the left valve, oblique at an angle of about 40° with the hinge; length nearly twice the height; ante-byssal margin slightly oblique, curving gently into the sinus; ventral margin broadly rounded, straighter toward the posterior end, which is acutely recurved.

Left valve ventricose, the greatest convexity a little above the middle; abruptly rounded or sub-angular along the post-cardinal slope, and the elevation is continued into the angular posterior extremity. Right valve much less convex.

Hinge-line straight, length more than two-thirds the length of the shell.

Beaks at about the anterior third of the hinge-line, very prominent and incurved over the hinge in the left valve. In the right valve the beak is subdued, not rising above the hinge-line. Umbo very gibbous in the left valve, subtending an acute angle.

Anterior end moderately large, limited by a very broad, shallow, slightly oblique byssal depression; extremity flattened, acute, defined by an oblique constriction in the margin just below the cardinal line. Wing of medium size, joining the body of the shell a little above the posterior extremity:

the limiting furrow distinct; the fold gentle and the upper part of the wing tlat or slightly convex; margin obliquely truncate, concave just below the hinge; extremity slightly produced.

Surface marked by fine uniform radii on the body and wing, which are nearly obsolete on the anterior end, and sometimes interrupted on the body by varices of growth; also by fine concentric striæ which are acutely recurved over the angular posterior slope of the body, and crowded into fascicles at irregular intervals, producing an undulated appearance.

Interior unknown.

A large left valve has a length of 52 mm, height 28 mm, and hinge-line 36 mm. A right valve in the same association has a length of 40 mm, height 20 mm, and hinge-line 33 mm.

This species somewhat resembles *P. trigonalis*, but the posterior extremity is more produced, and the wing more obliquely truncate on the margin. The right valve in general aspect resembles the right valve of *P. alata*, but the left valve is very dissimilar. The distinguishing characters are its large rhomboidal form, extreme gibbosity and arcuation of the left valve.

Formation and locality. In a compact sandstone of the Upper Cheming group, in the lower beds as seen at Warren, Pa.

Ртуснортекіл spatulata, n. sp.

PLATE LXXXV, FIG. 20,

SHELL large, clongate, rhomboidal; body sub-elliptical, oblique at an angle of about 30° with the hinge; length more than one-third greater than the height; ante-byssal margin oblique, gently curving into the sinus, thence extending into the broadly curved basal margin; posterior end rectangularly or acutely recurved.

Left valve moderately convex, slightly gibbons above. Right valve depressed-convex, more sub-angular along the post-cardinal slope, and smaller than the left.

Hinge-line straight, length about one-seventh less than the greatest length of the valve.

Beaks at about the anterior fourth, prominent and incurved over the hingeline in the left valve; depressed in the right valve and not rising above the eardinal line. Umbonal angle nearly rectangular.

Anterior end large, limited by a broad, slightly oblique, undefined byssal depression; extremity acute and nasute. Wing elongate triangular, joining the body at the posterior end; the dividing furrow distinct in the left valve, more conspicuous in the right; the fold is not defined in the left valve, and is strongly marked in the right; margin nearly vertically truncate; extremity not perceptibly produced.

Test thin, marked by fine radii, which are conspicuous upon the body and wing, and obsolete on the anterior end and byssal depression. The surface is also marked by fine concentric striæ, which are crowded into fascicles, giving an apparent undulation to the surface from the umbo to the lower extremity, especially in the right valve. At the post-basal margin the striæ are recurved at a little less than a right angle in the left valve, and more acutely in the right valve, and they are strongly lamellose on the anterior end.

Interior unknown.

The specimen described has a length of 56 mm, height 30 mm, and hinge-line about 48 mm.

This species resembles *P. lata*, and also some forms of *P. Sao*, but it is much more elongate, the valves more depressed, the wing narrower and longer.

Formation and locality. In the Upper Chemung group at Warren, Pa.

Ptychopteria lata, n. sp.

PLATE LXXXV, FIGS, 23-25.

Shell large, rhomboidal; body sub-elliptical, very oblique, making an angle with the hinge of nearly 40°; height equal to about two-thirds of the length; ante-byssal margin oblique, curving into the shallow sinus, from whence the

basal margin is broadly rounded; posterior extremity recurved at a little less than a right angle.

Left valve more convex than the right and gibbous above, obscurely angular along the post-cardinal slope. This difference in the valves is also shown in the direction of the strike of growth.

Hinge-line straight, about three-fourths as long as the length of the shell. Beaks near the anterior fourth of the hinge, prominent in the left valve, acute, arching over the cardinal line; in the right valve depressed, rising only as high as the hinge. Umbonal region of the left valve moderately gibbous, subtending an acute angle.

Anterior end short, small, limited by an oblique byssal depression which extends along the base about one-third the length of the shell; extremity acute. Wing large, extending along the shell to near the posterior extremity: margin obliquely truncate, coneave just below the hinge-line, which is abruptly produced.

Test thin, marked by fine, interrupted or undulated radii, which are more strongly marked on the body and wing, and obsolete on the anterior of the valve; the surface is also marked by fine concentric striæ, which are crowded into fascicles at unequal distances, undulating the surface; they turn abruptly ontward, just below the hinge, and are lamellose on the anterior part of the valve.

Interior unknown.

A specimen preserving both valves has a length of 45 mm., height 28 mm., hinge-line 35 mm. The right valve is somewhat smaller. Another specimen has a length of 42 mm., height 28 mm., hinge-line 36 mm.

This species resembles in form *P. Sao*, but is larger, the wing furrow more strongly defined on the left valve, the concentric lines more acutely recurved at the basal angle, and the radii are finer and more numerous.

Formation and locality. In the Upper Cheming group, the middle beds of the series, as seen at Warren, Pa.

Ptychopteria perlata, n. sp.

PLATE LXXXV, FIGS, 38, 39,

Shell large, rhomboidal; body ovate, oblique; length one-sixth greater than the height; anterior and basal margins broadly curved; posterior end angular.

Left valve very convex, gibbous above. Right valve somewhat gibbous above, having a convexity of about one-half that of the left valve.

Hinge-line straight, nearly equal to the length of the shell.

Beak at about the anterior third of the cardinal line, prominent and arching over the hinge in the left valve. Umbo gibbous in the left valve and convex in the right, subtending an acute angle.

Anterior end large, obscurely defined by a shallow byssal depression, which is obsolete in the right valve; margin convex; extremity acuminate. Wing broad triangular, joining the body at the posterior end; the furrow and fold are stronger in the left valve; margin slightly convex below, inclining a little forward; extremity produced, acute-angular.

Surface of the left valve marked by fine, close, rounded radii, which are often interrupted by the concentric lamellæ. The radii are finer upon the wing, obsolete upon the anterior end, and scarcely present on the right valve. The concentric lines of growth and lamellæ, give an irregularly undulating appearance to the surface.

Interior unknown.

A left valve has a length of 31 mm., height 26 mm., and hinge-line 30 mm. A right valve measures 33 mm. in length, 27 mm. in height, and hinge-line 32 mm.

This species is a shorter, more creet form than *P. lata*, and the left valve is more convex and broader below.

Formation and locality. In the upper beds of the Cheming group at Warren, Pa.

Ртуснортекіа Тиаца, n. sp.

PLATE LXXXV, FIGS. 32, 33.

Shell of medium size, rhomboidal; body ovate, oblique at an angle of about 45° with the cardinal line; length one-third greater than the height; anterior and basal margins broadly rounded, slightly impressed by the byssal sinus; post-basal extremity sub-angular, abruptly recurved.

Left valve extremely gibbous, the point of greatest convexity is onethird of the height from the beak. Right valve convex on the umbo, depressed-convex below.

Hinge-line straight, a little less than the greatest length of the shell.

Beak situated at the anterior third of the hinge, prominent in the left valve, curving over the hinge-line. Umbonal region abruptly gibbous in the left valve, distinctly limited, subtending an acute angle.

Anterior end comparatively large, limited by a nearly vertical shallow byssal depression; margin convex; extremity acute. Wing small, distinctly limited by the post-umbonal furrow; margin obliquely truncate, a little convex; extremity obtuse-angled.

Surface of both valves marked by fine radii originating on the umbo, becoming stronger on the lower part of the body, less conspicuous on the wing, and obsolete on the anterior end; and by lines of growth which are lamellose on the anterior side and produce unequal concentric ridges on the body of the valve.

Interior unknown.

A left valve has a length of 25 mm., height 17 mm., and hinge-line 23 mm. A small right valve has a length of 20 mm., height 13 mm., and hinge-line 16 mm.

This species resembles P, perlata but the wing is comparatively smaller, extremity not acuminate, and the umbo more gibbous.

Formation and locality. In a sandstone of the Upper Chemung group at Alleghany Springs, Warren county, Pa.

Ptychopteria gibbosa, n. sp.

PLATE LXXXV, FIG. 5.

Shell small, rhomboidal; body broad-ovate, oblique at an angle of about 45° with the hinge-line; length not more than one-seventh greater than the height; ante-byssal margin oblique, curving into the marked sinus, thence along the base to the nearly rectangularly recurved posterior extremity.

Left valve very convex, gibbous on the umbo and in the middle. Right valve unknown.

Hinge-line straight, nearly as long as the length of the shell.

Beaks a little anterior to the middle of the hinge; very prominent in the left valve and arching over the hinge. Umbonal region ample, very gibbous, obscurely angular along the posterior slope, subtending an acute angle.

Anterior end somewhat large, gibbous, and separated from the body of the shell by a nearly vertical sulcus; extremity acute and nasute. Wing of medium size, joining the body at the posterior end; the furrow and fold are very conspicuous, the fold somewhat broader and nearly equal to the portion of the wing above: margin almost vertically truncate; extremity apparently not produced.

Test thin, marked by fine radii and concentric striæ. The concentric lines are crowded into fascicles, producing an undulated appearance; and are strongly lamellose on the anterior end; the radiating striæ are distinct upon the body of the shell, obscure on the wing, and obsolete on the anterior end.

Interior unknown.

A specimen of the left valve has a length of 26 mm., height 15 mm., hinge-line 22 mm. Another has a length of 20 mm., height 13 mm., hinge-line 18 mm.

This species is distinguished by the sub-central position of the beak, and the great prominence of the umbo; the marked byssal depression, and strong furrow and fold of the wing.

Formation and locality. In the upper beds of the Chemiung group at Warren, Pa.

Ртуснортекіа цовата, n. sp.

PLATE LXXXV, FIG. 37.

SHELL small, sub-rhomboidal; body broadly ovate, oblique at an angle of about 55° with the cardinal line; length somewhat greater than the height; anterior margin sub-truncate; base broadly rounded; posterior margin rectangularly recurved into the wing.

Left valve very gibbous; the point of greatest convexity is just below the umbo. Right valve unknown.

Hinge-line straight, length nearly equal to the length of the valve.

Beak situated anterior to the middle of the hinge, prominent, inclined forward, and arching over the margin of the valve. Umbonal region ample, gibbous, subtending an acute angle.

Anterior end large, limited by a broad, undefined byssal depression; margin convex; extremity apparently obtuse. Wing small, joining the body at the posterior end, strongly limited by a deep furrow and very marked alar plication; margin nearly straight; extremity angular.

Surface marked by fine radiating striæ which become finer on the wing and anterior end; and by striæ of growth which are somewhat lamellose on the anterior of the shell.

Interior unknown.

A left valve of this species has a length of 13 mm., height 10 mm., hingeline 11 mm.

This species differs from *P. gibbosa* in its shorter, truncate anterior end, and stronger fold on the wing, which is comparatively stronger than in any species yet observed.

Formation and locality. In the sandstones of the Upper Cheming group, Warren county, Pa.

Ptychopteria Vanuxemi, n. sp.

PLATE LXXXV, FIG. 36,

Shell large, sub-triangular; body narrow-elongate, sub-cylindrical, oblique at an angle of nearly 30° with the hinge-line; ventral margin very long and gently curving; posterior margin abruptly and acutely recurved.

Left valve very convex along the axis of the body. Right valve unknown. Hinge-line straight, length more than one-fourth greater than the height, or about two-thirds the entire length of the shell. Umbonal angle very acute.

Anterior end unknown. Wing very large, triangular, joining the body near the posterior end; the furrow and fold obscure; margin obliquely truncate to near the hinge, where it is concave and abruptly recurved into the produced extremity.

Test thin, marked by strong radii, and by fine, sharp, equidistant, lamellose concentric striæ. The concentric striæ are crowded and somewhat fasciculate on the posterior and the wing, giving an undulated or imbricated appearance. The rays are very strong over the middle of the body, and subdued on the wing and basal side, and are distinctly crenulated by the elevated concentric lines, with the interspaces cancellated.

Interior unknown.

The specimen described has a length of 70 mm., height 34 mm., and hinge-line about 44 mm.

This species is conspicuously distinct from any other; in outline it approaches some of the extreme forms of *Pteronites*.

Formation and locality. In the highest beds of the Upper Cheming group at Warren, Pa.

Ptychopteria expansa.

PLATE XXIII, FIGS, 10, IL.

Phychopteria erpansa, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 23, tigs. 10, 11. Jan., 1883.

Shell of medium size, sub-rhomboidal; body ovate, oblique at an angle of about 60° with the hinge-line; length one-fifth greater than the height; ante-byssal margin oblique, gently curving into the shallow sinus; basal margin broadly rounded to the base of the wing.

Left valve convex below, gibbous above. Right valve unknown.

Hinge-line straight, central, length greater than the length of the valve.

Beak at about the anterior fifth of the hinge, inclined acutely forward, moderately prominent. Umbonal angle acute.

Anterior end small, surface convex to the nearly vertical byssal depression which extends half way to the base of the shell; extremity compressed and acute. Wing very large, triangular, extended, joining the body at the posterior extremity; the furrow obscurely marked; margin gently concave, extending backward; extremity produced.

Surface marked by regular strong radii and by concentric lines of growth. The concentric strike are sometimes erowded into irregular fascicles, giving an undulated appearance to the surface; the radii are strong on the umbonal slope, less conspicuous on the wing, and on the antero-basal portion they are interrupted, and oblique to those on the umbo.

Interior unknown.

The specimen described has a length of 27 mm, height 22 mm, and hingeline 30 mm.

This species is distinguished by its erect form, large and extended wing, and peculiar character of surface markings. The furrow of the wing is indicated only by a wider depression between the radii, and a stronger ray marks the fold.

Formation and locality. In a coarse sandstone of the Cheming group near Smethport, Pa.

GLYPTODESMA, HALL.

GLYPTODESMA ERECTUM.

PLATE XI, FIGS. 1-10; PLATE XII, FIGS. 1-3, 5-9; PLATE XIII, FIGS. 1-4, 12-15; PLATE XXV, FIGS. 14-17; PLATE LXXXVII, FIGS. 1-8; AND PLATE LXXXVII, FIGS. 1-3

Aricula erecta. Conrad. John. Acad. Nat. Sci., Phila., p. 238, pl. 12, fig. 5.—1842.

"cruciformis, Conrad. Geolog. Surv. N. Y.: Annual Report, p. 54.—1841.

Actinodesma erectum (Conrad), Hall. MS., Pal. N. Y.—1877.

"S. A. Miller, in Cat. Amer. Pal. Foss.—1877.

"cruciforme (Conrad), Hall. MS., Pal. N. Y.—1877.

"S. A. Miller, in Cat. Amer. Pal. Foss. 1877.

Glyptodesma erectum (Conrad), Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 11, figs. 1-10; pl. 12, figs. 1-3, 5-9; pl. 13, figs. 1-4, 12-15; pl. 25, figs. 14-17. Jan., 1883.

Shell large; body oyate, acute, erect or moderately oblique; wings more or less expanded, often greatly expanded; height frequently one-third greater than the length; basal margin more or less regularly rounded; anterior side broadly convex; posterior side nearly straight or slightly coneave.

Valves very unequal. Left valve varying from moderately convex to gibbous and arcuate. Right valve depressed-convex in the umbonal region, flat or coneave below; variable in convexity.

Hinge-line straight, often greatly extended, equalling or usually greater than the length of the valve.

Beak of left valve prominent, acute, inclined forward, rising above the hingeline, and situated anterior to the middle of the body of the shell. Umbonal region somewhat prominent, often gibbous, limited anteriorly by a distinct rounded sulcus, and posteriorly by an interruption and change in the direction of the striæ, which sometimes produces a defined line of separation. Umbonal angle acute.

Anterior wing auriform and small in young specimens, becoming expanded and variously extended in older specimens, limited by a distinct byssal depression; extremity rounded. Posterior wing large, triangular; margin concave; extremity often extended beyond the margin of the shell.

Test thick, marked by fine, irregular, concentric strike of growth which are sometimes raised into sharp lamellae, or crowded into prominent fascicles.

These strike become more conspicuous upon the margins and upon the wings, where they are often highly lamellose. The distant lamellae which mark the body of the shell are sometimes continued upon the hinge, and becoming stronger, curve over the margin, giving it a sharply annulated aspect, which, when preserved in the impression of the hinge-border, might be mistaken for a more important organic marking. Partially exfoliated shells show some obscure radiating lines which belong to the intimate shell-structure, and are not external. (These strike are too conspicuously represented in figure 6 of plate xii.)

Posterior muscular impression situated near the middle of the posterior slope, and marked by irregular vascular striæ; from the lower anterior side of this impression the pallial line extends slightly downward, curving forward, and continuing in a line nearly parallel to the margin it terminates in a small muscular impression within the rostral cavity. The pallial line is frequently pitted or interrupted in its course, and from these pits radiating grooves extend toward the margin of the shell.

Ligamental area extending the entire length of the hinge, comparatively wide, grooved longitudinally with fine, continuous parallel lines. Hinge with one or two linear, slightly oblique, lateral teeth on the posterior side, and with numerous erect or oblique irregular folds along the cardinal line below the ligamental area, which terminate on the inner margin in distinct crenulations. The cardinal wrinkles are smaller and more regular anteriorly, becoming large and irregular posterior to the beak.

Three large specimens have the following respective dimensions: length 90, 70, and 81 mm., height 100, 99, and 81 mm.; hinge-line 100, 90, and 90 mm. An example of medium size has a length of 55 mm., height 76 mm., and hinge-line 48 mm. A large, erect individual measures 72 mm. in length, and 90 mm. in height. A small right valve has a length of 23 mm., height 27 mm., and hinge-line 33 mm.

This is an abundant species and attains a very large size in older individuals. In its different conditions of growth and preservation, it presents a very great variety of aspect, and it becomes extremely difficult to determine the limits

of the species. In the young shell the posterior wing is proportionally more extended than in older individuals, while the anterior wing is usually smaller. During the progress of growth, both wings often become extravagantly developed, and the form and proportions of these parts cannot be relied upon for specific distinctions. The characteristic forms have the body nearly erect, with the umbo and beak directed slightly forward; but associated with these, are other forms which present a considerable degree of obliquity in the body of the shell, and while there seem to be no constant marks of specific distinction, it is extremely unsatisfactory to group them all under one species.

The interior characters also present considerable differences, the number of lateral teeth varying from one to three; the cardinal wrinkles and crenulations not only vary in number and strength, but in their direction, which is vertical or oblique. There is also a very great difference in the width of the ligamental area.

Formation and localities. In the shales and shaly sandstones of the Hamilton group, from the eastern limit of the formation as far west as Canandaigua lake; it is extremely abundant in Albany and Schoharie counties; Cazenovia and Hamilton, in Madison county, and at Pratt's falls, in Onondaga county, N. Y. This species is also found in a cherty limestone in Clarke county, Indiana; and in similar conditions and associations at several localities in Ohio.

GLYPTODESMA ERECTUM, VAR. OBLIQUUM.

'PLATE XII, FIG. 4; AND PLATE XIII, FIGS. 5-11.

Glyptodesma erectum, var. obliquum. Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 12, fig. 4; pl. 13, figs. 5-11. Jan., 1883.

This variety possesses the essential characters of the typical forms of the species. The hinge, test, etc., are similar, but the body of the shell is distinctly oblique; the wings are less developed, and the anterior wing, especially, has not the great extension often observed in the erect forms.

The specimens of this variety are uniformly smaller. They have been observed mainly in the soft shales at Pratt's falls, Onondaga county, while the large erect forms are common in the coarse shales and grits of the group in the eastern portion of the State, and in Madison county.

In examining and comparing the extreme forms, the difference is striking and distinctive. (For example, the erect forms on plate xi, and the oblique forms, figures 5 to 11, plate xiii.) But in the study and comparison of a series of several hundred specimens, the intermediate forms appear to unite the whole under a single species.

To facilitate the examination, the oblique forms, represented in figures 5-11 of plate xiii, are here designated as G. erectum, var. obliquum.

The description of Avicula erecta, and A. cruciformis, given by Mr. Conrad, are as follows, loc. eit.:

"Avicula erecta, pl. 12, fig. 5.—Direct; independent of the wings, of ovate acute outline; left valve ventricose, concentrically wrinkled, or marked with lines of growth; apex prominent, narrow, acutely rounded; posterior wing "elongated, pointed; basal margin uniting with the lateral margins in a regular "enrye or arch.

Locality—Hamilton, Madison county, New York.

"Avicula cruciformis, Conrad, loc. eit.: "Elevated, with both ears greatly "elongated. Locality—Near Oneonta: This species is remarkable for the great "proportional height; very little oblique. Height 3½ inches."

The name of A. cruciformis has precedence in point of time, but the name of A. erecta has been adopted because the description and figure entitle it to recognition, and the former name is only applicable to the more extravagant forms of the species illustrated on plates xi and xii.

GLYPTODESMA OCCIDENTALE.

PLATE XV, FIG. 12; AND PLATE LXXXVI, FIG. 9.

Glyptodesma occidentale, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 15, fig. 12. Jan., 1883.

Shell large, broadly ovate; body nearly erect; height and length about equal; margins regularly curved.

Left valve very convex, gibbous on the umbo. Right valve unknown.

Hinge-line straight, equalling or greater than the length of the shell.

Beak anterior to the middle of the shell, directed slightly forward, acute and prominent. Umbonal region gibbous, defined anteriorly by the broad sulcus, and on the anterior side sloping abruptly to the wing.

Anterior wing short, defined by a deep sulcus and a marked byssal sinus. Posterior wing large, depressed-convex, much extended, joining the body of the shell below the middle, and defined only by the recurving of the striæ; margin concave; extremity acute.

Test thick, marked by numerous fine strike of growth, which at intervals are crowded into fascicles, producing an undulating surface. The strike are more closely arranged, and become lamellose on the anterior part of the shell. On the posterior wing the strike are regular, and at distant intervals a single strike becomes sharply elevated.

Interior unknown.

The specimen of this species described has a length 60 mm., height 66 mm., and hinge-line equal to, or greater than the length of the shell.

This species resembles *G. erectum*, but appears to be a more robust form; the shell is more orbicular, the umbonal region more gibbous, the surface more rugose from the undulations of the fascicles of striæ, and the limitation between the body and the posterior wing is less strongly defined.

Formation and localities. In the limestone of the Upper Helderberg group at the falls of the Ohio, near Louisville, Kentucky, and in Clarke county, Indiana.

LEIOPTERIA, HALL.

LEIOPTERIA LÆVIS.

PLATE XVII, FIGS, 5-11; AND PLATE XX, FIG. 5.

Avicula lavis, Hall. Geolog. Surv. N. Y.: Rep. Fourth Dist., p. 181. 1843.

Pteronites lavis, (Hall) S. A. Miller. Cat. Amer. Pal. Foss., p. 202. 1877.

Leiopteria lavis, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 17, figs. 5-11. Jan., 1883.

Shell small, sub-rhomboidal; body obliquely ovate; length and height nearly equal; greatest length below the middle; margins regularly rounded, somewhat extended on the post-basal side.

Left valve more convex than the right; the greatest convexity in both valves is above the middle.

Hinge-line straight on the posterior side of the beak, turning abruptly downward in front; entire length greater than the length of the shell.

Beaks obtuse, rounded, inclined forward, situated at the anterior third of the shell, that of the left valve quite prominent. Umbonal region of left valve prominent, subtending an acute angle.

Ear triangular, nearly equilateral, with a strong angular fold along the middle, separated from the body of the valve by a distinct rounded sulcus and broad byssal sinus; margin rounded; extremity obtuse. Wing triangular, flat, limited by the post-umbonal slope; margin concave; extremity acute.

Test thin, marked with distinct concentric striæ of growth, which are crowded and conspicuous on the wings. There are often obscure traces of radii, which are more distinct on the wing in casts or exfoliated specimens.

Ligamental area narrow, with a single distinct groove. Some specimens apparently indicate the existence of an oblique lateral tooth on the posterior side of the umbo.

One specimen has a length of 11 mm., height 12 mm., hinge-line about 10 mm. Another has a length of 10 mm., height 11 mm., and hinge-line 12

mm. A small specimen is 8 mm. in length, 9 mm. in height, and hinge-line 10 mm.

Formation and localities. In the Marcellus shale at Littleville, Livingston county; Alden, Erie county, and East Bloomfield, Ontario county, N. Y.

LEIOPTERIA CONRADI.

PLATE XX, FIGS. 1, 2, 4; AND PLATE LXXXVIII, FIGS. 1-4.

Leiopteria Conradi, Hall. Pal. N. Y., vol. v., pt. 1. Plates and Explanations: Pl. 20, figs. 1, 2, 4, (5 in error). Jan., 1883.

Shell above the medium size, sub-rhomboidal; body oblique-ovate; length a little greater than the height; anterior margin straight, nearly vertical; basal and posterior margins regularly rounded.

Valves sub-equally convex; the left valve somewhat more convex than the right.

Hinge-line straight, longer than the length of the valve, greatly extended posteriorly.

Beaks acute, directed forward, prominent, situated near the anterior end of the shell. Umbonal region gibbous (in well-preserved shells), moderately convex below, subtending an acute angle.

Ear short, separated from the valve by a rounded depression or sulcus, marked by a shallow, elongate byssal sinus; extremity rounded. Wing triangular, much extended; margin concave; extremity acuminate.

Test, as indicated by easts or partially exfoliated specimens, marked by fine, closely arranged, concentric lines of growth, which at irregular intervals are crowded and raised into rounded or sub-angular fascicles, giving the surface a decidedly undulated aspect. The striæ become more crowded upon the cardinal expansions, especially upon the ear.

Ligamental area marked by a single longitudinal groove parallel to the hinge-line.

Two specimens of the left valve have respectively the following dimensions: length 39, and 42 mm., height 32, and 36 mm., hinge-line 42, and 47 mm.

This species bears some general resemblance in form to Actinopteria decussata and A. Boydi, but is distinguished by the absence of rays. It differs from L. Greeni, fig. 9, pl. xx, in its more oblique form and greater proportional length.

Formation and localities. In shales of the Hamilton group, on the shore of Canandaigua lake, and at Bellona, Yates county, N. Y.

LEIOPTERIA GREENI.

PLATE XX, FIGS. 9, 12; AND PLATE LXXXVIII, FIGS. 21, 22.

Leiopteria Greeni, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 20, figs. 9, 12. Jan., 1883.

Shell large, sub-rhomboidal; body moderately oblique, broadly ovate; length a little greater than the height; margins regularly rounded, somewhat extended posteriorly.

Valves moderately and nearly equally convex; similar in character.

Hinge-line straight, equalling or greater than the length of the shell.

Beaks acute, anterior, inclined forward, arching over the hinge in the left valve; less prominent in the right.

Ear short, limited by a sulcus and sinus which is deeper in the right valve. Wing large, triangular, defined only by the abrupt bending of the striæ; margin concave; extremity acute.

Test thin, marked by numerous, closely arranged, concentric lines of growth, and, at somewhat regular intervals, by sharp, projecting lamellose striæ; and corresponding with these, are regular concentric undulations, which are shown strongly on the cast, and but partially seen on the exterior surface. The striæ mark the wing in the same manner as the body, and are crowded on the ear.

Ligamental area narrow, marked by a single groove.

A large specimen measures 57 mm, in length, 51 mm, in height, hingeline 58 mm.

This species resembles L. Conradi, but is broader, with comparatively greater height, less obliquity, and less extended posterior wing.

Formation and localities. In the shales of the Hamilton group at Bellona, Yates county, and on the shores of Cayuga and Canandaigua lakes, N. Y.

LEIOPTERIA RAFINESQUII.

PLATE XV, FIG. 11; PLATE XX, FIGS 6, 7; AND PLATE LXXAVIII, FIGS. 27, 28

Leiopteria Rafinesquii, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 15, fig. 11; pl. 20, figs. 6, 7. Jan., 1883.

Shell of medium size, sub-rhomboidal; body rather narrow above, obliquely ovate; height equalling or greater than the length; margins regularly curved; the post-basal side extended; anterior side sometimes nearly straight for a short distance below the ear.

Left valve convex, gibbous on the umbo. Right valve less gibbous. The right valve supposed to belong to this species is convex on the umbo, and of moderate convexity below; the height is considerably greater than the length, and the body of the valve less distinctly defined than in the left valve.

Hinge-line straight; from the anterior side of the beak to the posterior extremity it is about equal to the length of the shell.

Beak of the left valve acute, directed forward, very prominent, situated at the anterior extremity of the shell. Umbonal region gibbons, subtending an acute angle.

Ear short, convex, obtuse, with a broad undefined vertical sulcus and shallow byssal sinus. Wing moderately large, flat; margin concave; extremity acute.

Test thin, marked by regular, concentric lines of growth, which are more erowded upon the cardinal expansions. The striæ are raised at intervals into strong, elevated lamellæ, which are conspicuous on the east, and more erowded and prominent on the anterior side. The right valve referred to this species is marked by concentric wrinkles, which are well-preserved on the anterior side, with distant, elevated, lamellose striæ on the wing and the margin of the hinge.

Internal characters unknown. The ligamental area appears to be marked by a groove along the wing parallel to the hinge-line.

Three characteristic specimens have respectively the following dimen-

sions: length 39, 34, and 25 mm., height 41, 38, and 26 mm., hinge-line 37, 39, and 26 mm. The right valve, mentioned above, is 23 mm. in length, 25 mm. in height, and 23 mm. along the hinge-line.

This species resembles the two preceding, but the form of body is more narrowly ovate, the obliquity appears to be intermediate between the two; the ear is less strongly defined; the wing is comparatively narrower, and less extended at the extremity.

Formation and localities. In the shales of the Hamilton group, on the shores at Skaneateles lake; at Bellona, Yates county, and Leonardsville, Madison county, N. Y.; a single specimen from the Corniferous limestone of Delaware, Ohio, has been referred to this species.

Leiopteria Sayi, n. sp.

PLATE LXXXVIII, FIGS. 15-20.

Shell above the medium size, sub-orbicular; body very broadly ovate, searcely oblique; height greater than the length; margin nearly straight in front, thence regularly rounded.

Left valve very convex, gibbous in the umbonal region. Right valve smaller and less convex.

Hinge-line straight, longer than the length of the shell.

Beaks acute, situated near the anterior extremity of the hinge, prominent, inclined forward, arching over the hinge-line. Umbonal region ample, subtending a right angle.

Ear small, bending downward, defined by a broad, shallow sulcus. Byssal sinus narrow. Wing large, triangular, greatly extended along the hinge-line, defined by the retral bending of the striae; margin coneave; extremity acute. The wing of the right valve is very broad, flat, and much extended; not distinctly defined.

Surface marked by fine, closely arranged strike of growth, with distant, elevated lamellæ, which are extensions of strong fascicles of strike. These leave angular concentric folds and undulations in the casts. The strike are

strongly marked on the cardinal expansions and over the hinge-margin. In well-preserved specimens the undulations are stronger upon the middle of the valve, and less marked upon the anterior side and the wing. In the right valve they are much more regular and subdued.

Interior characters unknown. Ligamental area marked by a distinct groove parallel to the margin.

The largest specimen has a length of 50 mm, height 46 mm, hinge-line about 45 mm. A small specimen measures 26 mm, in length, 39 mm, in height, hinge-line imperfect. Another specimen is 26 mm, in length, 33 mm, in height, hinge-line 27 mm. A right valve is 33 mm, in length, height about the same, hinge-line 41 mm.

This form resembles, in general surface characters, the three preceding species, but differs by the more erect body and sub-orbicular form. In general aspect it resembles GLYPTODESMA, and the surface markings are not very different, though none of the specimens show the hinge characters of that genus.

The description has been drawn from specimens preserved in fine calcarcous shale and in coarser arenaceous material, and the characters remain essentially the same in both.

In a single specimen from the arenaceous shales on the shore of Cayuga lake, at Norton's Landing, where the shell is partially exfoliated, the surface is marked by fine, concentric lines of growth, and more distant lamellose striae, which are about twice as numerous as in the typical specimens. These give a gently undulating character to the surface of the east of the left valve, instead of the abrupt angular folds of the typical specimens. In the right valve of the same specimen the striae on the umbo are similar, but more closely arranged, and on the lower portion, in the east, they exhibit the gentle undulations of the typical forms of the right valve.

Formation and localities. In shales of the Hamilton group, in Ontario county; Norton's Landing, Cayuga county; Bellona, Yates county, and in the coarse grits at Leonardsville, Madison county, N. Y.

Leiopteria Dekayi.

PLATE XIX, FIG. 1; PLATE XX, FIGS. 16-18; AND PLATE LXXXVIII, FIGS. 5-10.

Leiopteria Dekayi, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations; Pl. 19, fig. 1; pl. 20, figs., 16-18, (19 in error). Jan., 4883.

SHELL of medium size, sub-rhomboidal in general form; body narrowly ovate, oblique; length about equal to the height; anterior margin nearly vertical for one-third the length of the shell, thence broadly rounded over the basal margin and abruptly recurved at the post-basal extremity.

Left valve convex, gibbous on the umbo. Right valve smaller and less convex; the limitation of the wing not strongly defined.

Hinge-line straight, length a little less than the length of the shell measured from the anterior side of the beak to the extremity of the wing.

Beaks anterior, acute, prominent, inclined forward. Umbonal region gibbous above, regularly convex below, subtending an acute angle.

Ear bending downward, with a strong fold in the upper part, limited by a broad undefined sulcus and shallow byssal sinus. Wing triangular, flat, defined by the abrupt retral bending of the striæ and a depressed line along the post-eardinal slope; margin concave; extremity acute.

Test thin, marked by fine regular concentric striæ, which at unequal intervals are crowded into fascicles, giving an undulated aspect to the surface of the east; in old specimens, more crowded on the anterior side and ear, and on the wing usually regular, sometimes becoming a little fasciculate on the margin.

This description of the surface is taken from casts or partial casts which preserve more or less the surface markings. In a few younger specimens from the shales, the surface shows fine regular striae which gradually become fasciculate as the shell increases in size.

Ligamental area narrow, marked by fine strice; below this area is a narrow oblique fold or lateral tooth.

The three specimens figured on plate xx, have respectively the following dimensions: length 37, 31, and 29 mm., height 37, 30, and 30 mm., hinge-

line 31, 21, and 23 mm. A smaller specimen has length of 17 mm., height 16 mm., hinge-line 15 mm.

This species resembles in form *L. Conradi* and *L. Rafinesquii*, but there are some differences in shape and obliquity, and more decidedly in surface characters. The wing is not so much extended as in *L. Conradi*, the strice are more abruptly recurved, and the post-cardinal slope is more strongly defined. There is a general resemblance with *L. Bigsbyi*, but the body and hinge-line are longer, the body narrowing more rapidly from the base, and the strice are equal and uniform.

Formation and localities. In the soft shales of the Hamilton group; at Skane-ateles and Cayuga lakes; and in the upper coarse beds and lower shales at Pratt's falls, Onondaga counity; also at Schoharie, N. Y.—It is widely distributed from the eastern to the central portion of the State.

LEIOPTERIA BIGSBYI.

PLATE XX, FIGS. 3, 11, 13-15; AND PLATE LXXXVIII, FIG. 23.

Leiopteria Bigshyi, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 20, figs. 3, 11, 13-15. Jan., 1883.

SHELL larger than medium size, sub-rhomboidal; body ovate, oblique; height greater than the length; anterior margin nearly vertical for about half the height of the shell, thence regularly rounded along the base; posterior side moderately extended.

Left valve gibbous upon the umbo, less convex towards the base. Right valve gibbous on the umbo, depressed-convex below, shorter than the left valve.

Hinge-line straight, equalling or less than the length of the shell.

Beaks anterior, acute, prominent, rising above the hinge-line, inclined forward. Umbonal region prominent, subtending an angle of about 55°.

Ear short, bending moderately downward, with a strong fold at the upper side, limited by a broad, undefined sulcus. Byssal sinus shallow. Wing triangular, wide, nearly flat; margin concave: extremity acute. The wing of the right valve is less defined than in the left, and the byssal sinus is a little deeper.

Test thin; specimens partially exfoliated, or occurring in the condition of casts, show sharply elevated, lamellose, concentric striae, which are very distinct on the wings, and crowded and somewhat fasciculate on the anterior side and ear. No intermediate finer striae have been observed. In well-preserved specimens the sharp lamellæ have undulating margins.

Interior unknown. Ligamental area marked by a single groove.

A large specimen has a length of 43 mm., height 50 mm., hinge-line 37 mm. Another example has a length of 32 mm., height 33 mm., hinge-line 30 mm. In the younger shells the height is proportionally somewhat less than in the older ones.

This species, compared with the preceding, has a greater height of body and shorter hinge-line, and differs in the conspicuous, sharp, concentric lamellæ. In this species the concentric striæ do not produce the folds and undulations which are characteristic of *L. Rafinesquii* and *L. Greeni*.

Formation and localities. In shales of the Hamilton group at Pratt's falls, Onondaga county, and in the coarser beds at Schoharie, N. Y.

LEIOPTERIA MITCHELLI.

PLATE XX, FIG. 87 AND PLATE, LXXXVIII, FIG. 26.

Leiopleria Mitchelli, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 20, fig. 8. Jan., 1883.

SHELL large, sub-rhomboidal; body ovate, moderately oblique: height greater than the length; anterior margin nearly vertical from the ear for about half the height, then broadly curving to the post-basal side, thence more abruptly bending, making the posterior end slightly extended.

Left valve gibbous on the umbo, sloping from highly convex above to moderately convex below. Right valve unknown.

Hinge-line straight, equal to the length of the valve.

Beak auterior, acute, inclined forward, prominent. Umbonal region prominent, subtending an acute angle.

Ear short, limited by an undefined sulcus and shallow byssal sinus. Wing large, triangular, nearly flat, defined by the retral curving of the lamellose striæ; margin moderately concave; extremity abruptly acute.

Test thin, marked by regular concentric lines of growth, with distant, lamellose striæ, which are raised into thin, sharp elevations corresponding with the concentric folds or undulations of the shell. The cast shows only the undulations. On the anterior margin and wing, the lamellæ are closely crowded, producing a varicose appearance. They are more closely arranged upon the wing than on the valve, making a gentle retral curve and becoming very conspicuous on the hinge-margin.

Interior unknown. Ligamental area narrow.

 Λ left valve has a length of 46 mm., height 49 mm., hinge-line about 47 mm.

This species, in general proportions, resembles A. Bigsbyi; it differs in the larger and more extended posterior end, with strice nearly vertical or gently curving, except at the hinge margin; the body wider above, and the anterior basal margin less convex. With a single exception, the specimens of L. Bigsbyi occur in arenaceous beds, while this species is common both to the softer shales and in the coarser beds.

Formation and localities. In soft shales of the Hamilton group, from loose masses of rock at the south end of Seneca lake, and in the coarse grits, at Schoharie, N. Y.

Leiopteria Troosti, n. sp.

PLATE LXXXVIII, FIGS. 12, 13

Shell above the medium size, sub-rhomboidal; body broadly ovate, moderately oblique; height somewhat greater than the length; anterior margin, from the wing to about half the height, nearly vertical, curving broadly around the base, and more abruptly rounded behind.

Left valve moderately convex, gibbous on the umbo. Right valve unknown. Hinge-line straight, somewhat less than the length of the shell.

Beak anterior, acute, prominent, inclined forward, rising above the hinge. Umbonal region gibbous, abruptly limited on the anterior side by the suleus, and on the posterior side sloping rapidly to the wing.

Wing large, flat, triangular, joining the body of the valve below the middle of the height, limited by the gently retral curve of the striæ; margin moderately concave; extremity acute or uncronate.

Surface marked by regular, equidistant, indulating, lamelliform, concentric expansions, which become crowded, finer, and to some extent less undulated on the wing, stronger and very much crowded on the anterior of the shell. The undulations extend forward in an abrupt curve, bending gently backward, and being thus opposite and slightly imbricating, they give an appearance of radiation.

Interior unknown.

The specimen described has a length of 35 mm., height 37 mm., and hingeline about 29 mm.

In general aspect, this species resembles Actinopteria Boydi, but the body is much less oblique and wider below; the surface is without proper rays; the wing has only fine, crowded, concentric striæ; while in that species the wing is marked with strong radii and a few lines of growth.

These comparisons are made from similar easts of the interior of both species. Formation and locality. In the coarse grits of the upper part of the Hamilton group, in the northern part of Schoharie county, N. Y.

Leiopteria Leai, n. sp.

PLATE LXXXVIII, FIGS, 24, 25.

SHELL small, sub-rhomboidal; body broadly ovate, very moderately oblique; height much greater than the length; margin regularly rounded from above the middle on the anterior side, to a similar point on the opposite side of the valve; post-basal margin slightly produced.

Left valve very convex; gibbons from below the middle to the umbo. Right valve unknown.

Hinge-line straight, less than the length of the shell.

Beak anterior, acute, rounded, inclined forward, prominent. Umbonal region gibbous, subtending an acute angle.

Ear short, directed downward, limited by an undefined sulcus, with scarcely any evidence of a byssal sinus. Wing comparatively small, flat, not strongly defined, joining the body of the shell above the middle of its height; margin concave; extremity abruptly acute.

Test marked by fine concentric striæ, which, at intervals, are crowded into fascicles upon the body of the shell, giving an undulating surface. On the wings they are closely and evenly arranged.

Interior unknown.

One specimen has a length of 20 mm., height 25 mm., and hinge-line about 17 mm. A small specimen has a length of 13 mm., height 15 mm., and hinge-line 12 mm.

This species is more prominent on the umbo and more convex below than any of the forms described in this group; the wing is shorter and smaller, with less extension along the posterior slope. A young shell referred to this species and in the same association has a body less abruptly defined on the posterior side.

Formation and locality. In the coarser grits of the Hamilton group, in the southern part of Schoharie county, N. Y.

Leiopteria Gabbi, n. sp.

PLATE LXXXVIII, FIG. 14.

SHELL small; body ovate, very slightly oblique; height considerably greater than the length; anterior margin nearly erect for half the height of the valve, and regularly curving to the post-basal margin, which is scarcely produced.

Valves sub-equally convex; the greatest convexity being a little above the middle in the left valve, and on the umbo of the right valve.

Hinge-line not extended, less than the length of the shell.

Beaks acute, prominent, directed forward, anterior to the middle of the shell. Umbonal region gibbous, subtending an acute angle.

Ear small, straight on the upper margin; marked by an oblique fold, and separated from the body by an abrupt sulcus and a well-defined byssal sinus. Wing small, triangular, joining the body of the shell below the middle of its height, defined by a change in the direction of the surface striæ; margin gently concave; extremity acute.

Test thin, marked by fine concentric striæ, and at regular intervals by stronger elevated striæ, which give to the macerated shell, and the cast of the interior, a regular banded surface. These stronger striæ are closely arranged on the anterior side and car, while on the posterior side they preserve their equidistant character. The right valve is very distinctly marked by the elevated concentric striæ. In both valves there are radiating lines which apparently belong to the structure of the shell.

Interior unknown. Ligamental area narrow.

One specimen has a length of 13 mm., height 16 mm., hinge-line about 10 mm. Another example has a length of 12 mm., height 13 mm., and hinge-line about 11 mm.

The small size, erect ovate form, short hinge-line, the proportions of height and length, and the surface characters, distinguish this species from every other form here described.

Formation and localities. In the soft shales of the Hamilton group; shores of Canandaigua lake, and at Norton's Landing, Cayuga lake, N. Y.

Leiopteria Oweni.

PLATE XX, FIG. 10,

Leiopteria Oweni, Hall. Pal. N. Y., vol. v. pt. 1 Plates and Explanations: Pl. 20, fig. 10. Jan., 1883.

Shell quite large, sub-rhomboidal; body broadly ovate, oblique to the hingeline; length greater than the height; margins rounded, produced posteriorly. Left valve convex, umbo gibbous, beak elevated. Right valve concave below, flat above, becoming convex towards the beak, which is low and searcely reaches the hinge.

Hinge-line straight, about equal to the length of the valve.

Beaks anterior, acute, directed forward.

Ear large, extended, defined by a broad sulcus and marked byssal sinus. Wing large, expanded; margin concave; extremity abruptly acute.

Test thin, marked by fine concentric strike of growth, which on some parts of the surface are crowded into fascicles, producing ridges or undulations. These are somewhat regular over the whole of the left valve, and stronger on the anterior part; on the right valve they are without regularity. The right valve also shows radiating lines which appear to belong to the shell structure, and are quite conspicuous in partially exfoliated specimens. The strike are crowded and lamellose on the anterior margin and adjacent to the byssal sinus; on the wing they are closely and evenly arranged.

Interior unknown.

One of the imperfect specimens described has an approximate length of 61 mm., height 55 mm., and hinge-line about 55 mm.; the measurement along the axis of the body, from the beak to the post-basal margin, is 75 mm.

The two specimens observed are crushed, and the characters of the left valve are very much obscured, while the right valve preserves more nearly its true proportions. It differs from the other species of this group in the concave form of the right valve. In surface markings it is very similar to *L. Sayi*, but the concave right valve is a very distinguishing feature. The shell is large and thin, and has suffered compression and distortion in the process of imbedding in the soft shales.

Formation and locality. In the soft shales of the Hamilton group, Canandaigua lake, Ontario county, N. Y.

LEIOPTERIA CHEMUNGENSIS.

PLATE XXII, FIGS. 17, 18.

Aricula Chemingensis, Vanuxem. Geolog. Surv. N. Y.; Rep. Third Dist., p. 182, fig. 49, No. 3, 4842. Leiopteria nitida, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations; Pl. 22, figs. 17, 48, Jan., 1883.

Shell of medium size or larger, rhomboid-ovate; body elongate-ovate, oblique at an angle of about 60° with the hinge-line; length equal to more than four-fifths of the height; anterior margin nearly vertical for about one-half the height of the shell and broadly rounded on the base; post-basal margin abruptly rounded.

Left valve convex, gibbous in the umbonal region. Right valve smaller, less gibbous.

Hinge-line straight, a little longer than the height of the shell.

Beaks sub-anterior, inclined forward, acute, prominent, arching over the hinge. Umbonal region narrow, prominent, subtending an acute angle.

Ear of left valve small, bending slightly downward, defined by a broad distinct sulcus; extremity rounded. Ear of right valve flat. Byssal sinus shallow and broad, deeper in the right valve. Wing broad-triangular, joining the body below the middle of the length, limited by the abrupt bending of the striæ; margin deeply concave in the middle; extremity produced and acute.

Surface, in a partial cast, marked by fine concentric striæ, which are crowded and lamellose on the ear, distinctly marked on the wings, and appearing on the body as distinct undulations: these in the perfect shell may have been sharp lamelliform striæ.

Interior unknown.

A specimen of the left valve has a length of 30 mm., height 35 mm., hinge-line 47 mm.; the body from beak to post-basal extremity measures 43 mm.

The specimen figured is the original of Avicula Chemungensis, Vanuxem. It resembles L. Dekayi of the Hamilton group, but differs in its longer hinge-line, larger wing, and more acute beak, while the body of the shell is narrower.

In the volume of Plates and Explanations this species was referred to L. Dekayi in the absence of the original specimen, which has since been compared and found to belong to the Chemung group.

Formation and locality. In a slaty sandstone of the Cheming group, eight miles north of Binghamton, N. Y.

Leiopteria linguiformis, n. sp.

PLATE LXXXVIII, FIG. 29.

Shell above medium size, erect, sub-rhomboidal; body elongate-ovate, making an angle of about 60° with the hinge-line; length equal to three-fourths of the height; anterior margin nearly vertical from the byssal sinus to below the middle of the valve; basal margin broadly rounded; post-basal margin rapidly curving into the wing.

Left valve convex above, depressed-convex below. Right valve unknown. Hinge-line straight, nearly equal to the length of the shell.

Beak acute, erect, prominent, rising above the hinge-line. Umbonal region convex, subtending an acute angle.

Ear small, triangular, bending slightly downward, limited by a well-defined byssal depression; margin nearly straight; extremity rounded. Byssal sinus shallow. Wing broad-triangular, joining the body below the middle of the post-cardinal slope, not strongly limited; margin concave; extremity acute.

Surface marked by concentric strike which are strongly lamellose on the ear, the pallial margins and on the wing.

Ligamental area narrow, marked by two or three longitudinal grooves. Muscular impression oval, situated near the middle of the post-cardinal slope.

The specimen described has a length of 33 mm., height 42 mm., and hinge-line 32 mm.

This species differs from L. Chemungensis in its more erect form, and the ear is without the strong fold and marked sulcus of that species; the wing is also less extended and the margin less concave.

Formation and locality. In the Chemung group in the valley of Cayuta creek, Broome county, N. Y.

Leiopteria Torreyi, n. sp.

PLATE XXII, FIGS. 6, 7; AND PLATE LXXXVIII, FIG. 11.

Shell of medium size, rhomboidal, sub-falcate; body narrow-ovate, arcuate, oblique at an angle of less than 45° with the hinge; height equal to about two-thirds of the length; anterior and basal margins broadly curving from the byssal sinus; post-basal margin produced and abruptly recurved.

Left valve very convex, gibbous in the middle and above. Right valve unknown.

Hinge-line straight, about equal to the height of the valve.

Beak sub-anterior, directed forward, acute, prominent and arching over the hinge. Umbonal region narrow, ventricose, well-defined, subtending an acute angle.

Ear large, bending downward, marked by a strong oblique fold, limited by a broad, vertical byssal depression and shallow sinus; margin convex; extremity apparently obtuse. Wing joining the body above the posterior extremity, limited by the nearly vertical post-umbonal slope, which makes a more or less marked sulcus; margin concave; extremity produced, acute.

Surface marked by fine strike of growth which are somewhat regularly lamellose on the body of the valve.

A left valve has a length of 29 mm., height 22 mm., hinge-line 24 mm.

This species differs from *L. Chemungensis* in its proportionally greater length, narrower umbo, more convex and oblique left valve, and shorter wing.

Formation and locality. In a sandstone and conglomerate of the Chemung group near Panama, N. Y.

LEPTODESMA. HALL.

The species arranged under the generic designation of Leptodesma present a very remarkable assemblage of forms, beginning (as here arranged) with those resembling Avicula and passing through various phases in form, proportions, etc., until the wing becomes nearly obsolete, the byssal sinus obscure, and the anterior end rounded, and the entire shell assuming the form of Mytilus or Modiola, Sangunolites, Modiomorpha and allied genera. For convenience the species have been arranged into natural groups in the following order: a, spinifera; b, umbonata; c, rostrata: d, patulata; e, arcoidea; f, mytiloidea. These relations will be more fully explained under the generic description and discussions in the Introduction to this volume.

Section a, spinifera.

LEPTODESMA MARCELLENSE.

PLATE XVII, FIG. 12.

Leptodesma Marcellense, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 17, fig. 12. Jan., 1883.

Shell small, sub-rhomboidal; body obliquely ovate: height about two-thirds the greatest length; margin regularly rounded, extended posteriorly and continuing in a direct line to the beak.

Left valve moderately convex. Right valve unknown.

Hinge-line straight, greatly extended posteriorly, reaching beyond the margin of the valve.

Beak obtuse, prominent, nearly creet, situated on the anterior third of the hinge. Umbonal region prominent, sloping abruptly on the posterior, not well defined on the anterior side.

Anterior end limited by a shallow, obscure sulcus; margin regularly rounded. Wing narrow-triangular, much extended along the hinge, terminating in a mucronate process; margin deeply and acutely sinuate.

Test thin, marked by fine, closely arranged, concentric striæ, which are more crowded anteriorly; these are crossed by extremely fine radii, which are chiefly confined to the shallow sulcus, anterior to the beak, and are also obscurely marked on the wing.

Ligamental area marked by two strong grooves. Two oblique linear depressions along the posterior slope indicate the probable existence of lateral teeth. Other characters of the interior, unknown.

The specimen has a length of 11 mm., height 7 mm., hinge-line 12 mm.

This species bears some resemblance to several species in the Chemung group, but it is comparatively narrower and more oblique.

Formation and locality. In the Marcellus shale, Bloomfield, Ontario county. N. Y.

LEPTODESMA ROGERSI.

PLATE XXI, FIGS, 1-9.

Leptorlesma Rogersi, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 21, figs. 1-9. Jan., 1883.

SHELL of small or medium size, sub-rhomboidal; body ovate, very oblique; length greater than the height; anterior and basal margins broadly rounded; posterior margin extended and abruptly recurved.

Valves equally convex above. Right valve somewhat depressed below, comparatively higher than the left.

Hinge-line straight, longer than the length of the shell.

Beaks sub-anterior, obtuse, nearly erect, prominent. Umbonal region gibbous, oblique.

The anterior extremity is searcely alate or auriculate, consisting of a rounded extension, straight above and slightly sinuate at the base. Wing comparatively large, triangular, joining the body of the valve near the posterior extremity, defined by the crowding and curving of the concentric striæ; margin nearly straight for five-sixths of its extent, then aentely recurving; extremity prolonged into a mucronate spine which extends beyond the posterior limit of the valve. In the right valve the wing is less deeply sinuate.

Test thin, marked by closely arranged concentric striæ, which at irregular intervals are crowded into fascicles, producing a gently undulated surface. On the wing the striæ are closely arranged, and just below the hinge-line are turned backward along the spiniform extension of the wing.

Interior unknown. Ligamental area narrow, having several fine grooves parallel to the hinge.

One specimen has a length from beak to base of 24 mm., height 15 mm., hinge-line about 20 mm. The corresponding right valve has a length of 20 mm., height 15 mm., hinge-line 26 mm. The largest specimen observed has a length of 32 mm. height 21 mm., hinge-line, to the origin of the spine, 20 mm. Small specimens are often less than 10 mm. in length and height.

This species, occurring abundantly in the Hamilton group, closely resembles Avicula spinigera of Corrad, from the Chemung group. In the comparison of large numbers of specimens, the differences are so slight that specific distinction is not always apparent. The Chemung forms are usually more oblique, but this is not a constant character; the wing is smaller and less extended along the posterior slope; the right valve is narrower and more oblique, and the sinus in the margin of the wing is narrower and deeper than in the right valve of the Hamilton form.

Formation and localities. In the shales of the Hamilton group at Norwich, Chenango county; Middleville, Schoharie county, and Leonardsville, Madison county, N. Y.

LEPTODESMA SPINIGERUM.

PLATE XXI, FIGS, 10-13; AND PLATE LXXXIX, FIG. 1

Avicula spinigera, Conrad. Jour. Acad. Nat. Sci., Phila., vol. 8, p. 237, pl. 12, fig. 3.—1842.

Pteronites spinigerus (Conrad), S. A. Miller. Cat. Amer. Pal Foss., p. 202.—1877.

Leptodesma spinigerum (Conrad), Hall. Pal. N. Y., vol. v, pt. 1.—Plates and Explanations: Pl. 21, figs. 10-13.—Jan., 1883.

Shell of medium size, sub-rhomboidal; body ovate, oblique to the binge at an angle of about 45°; length one-third greater than the height; ante-by-sal

margin truncate at the extremity, curving below into the sinus; basal margin rounded, somewhat abruptly recurved posteriorly.

Left valve regularly convex below, gibbous above the middle. Right valve depressed-convex below and abruptly gibbous above.

Hinge-line straight, (and including the spine) equal to or greater than the length of the shell.

Beaks sub-anterior, prominent. Umbonal region abruptly gibbous, sub-tending an acute angle.

Anterior end short, defined by the oblique byssal depression which extends to more than one-third the length of the valve below the beak; extremity obtusely angular. Wing not large, joining the body nearly at the posterior third; margin oblique below, acutely recurved above, the greatest concavity being just below the cardinal extension; extremity produced into a long spiniform process.

Test thin, marked at irregular intervals by strong concentric lamellæ, with intermediate fine striæ. The lamellæ are stronger on the anterior side and obscure on the wing. The casts are often nearly smooth.

luterior unknown.

A specimen of medium size has a length of 29 mm., height 20 mm., hingeline to base of spine, 12 mm. A smaller specimen has a length of 20 mm. height 14 mm., hinge-line, to base of spine, 12 mm.

This species closely resembles L. Rogersi, but is distinguished by the oblique and more extended by sal depression, shorter wing, and more rounded basal margin.

Formation and localities. In shales of the Chemung group, on the Chemung river above Elmira, and along the Blossburg railroad near Painted Post, N. Y.

LEPTODESMA LONGISPINUM.

PLATE XXI, FIGS. 14, 17-19; AND PLATE LXXXIX, FIGS. 2-4.

Avicula longispina, Hall. Geolog, Surv. N. Y.: Rep. Fourth Dist., p. 262, fig. 3. 1843.
Pterinea longispina (Hall, S. A. Miller. Cat. Amer. Pal. Foss. 1877.
Leptodesma longispinum, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 21, figs. 14, 17-19.
Jan., 1883.

Shell above the medium size, sub-rhomboidal; body elongate-ovate, very oblique; length greater than the height, often nearly double; margin from the byssal sinus to beyond the base broadly rounded; posterior margin extended and abruptly recurved.

Valves, in young specimens, sub-equally convex; in older specimens the right valves are somewhat less convex.

Hinge-line straight; length equalling or greater than the length of the valve. Beaks anterior, prominent, obtuse, nearly erect, arching over the hinge-line. Umbonal region gibbous, subtending an acute angle.

Anterior extension scarcely auriculate, rounded in front, straight above. Wing small, very narrow-triangular; margin deeply sinuate, the bottom of the sinus being close beneath the hinge-line; extremity produced into an elongate spine.

Test thin, marked by fine, irregular, concentric strike of growth, which are abruptly recurved on the post-cardinal slope, and extend along the margin for nearly half the length of the body before recurving into the wing. The strike are more elevated and crowded on the anterior side.

The original specimen of this species has a greatest length from beak to base of 42 mm., height 24 mm., hinge-line about 38 mm. A small right valve has a length of 22 mm., height 12 mm., hinge-line 24 mm.

This species resembles L. Rogersi, but the shell attains a larger size; the body is more oblique to the hinge-line, and the posterior extremity more abruptly recurved; the wing is smaller and not extending so far down the body of the valve, the sinus is narrower with the deepest portion just beneath the hinge; the spine is stronger and more distinctly defined: the right and left

valves are the same in form; the sinus in the wing of the right valve is not so deep as in the left valve, but much deeper than in the right valve of that species.

The original specimen is illustrated in figure 14 of plate xxi, and figures 17, 18, 19 are right valves occurring in the same beds.

This form is associated with Avicula spinigera of Conrad, which is a smaller shell, less oblique, narrower, and with a more angular anterior extremity.

Formation and localities. In the Cheming group, at Painted Post, Steuben county, between Corning and Elmira, and at Cheming Narrows, N. Y.

Leptodesma Shumardi, n. sp.,

PLATE LXXXIX, FIGS 5, 6,

Shell of medium size, sub-rhomboidal; body narrow, very obliquely-ovate; length somewhat less than twice the height; margin very broadly curving from the anterior extremity to the base; basal margin rounded and abruptly recurved at the post-basal extremity.

Left valve quite convex; the greatest convexity about one-third the length of the valve below the apex. Right valve unknown.

Hinge-line straight: length about equal to the height of the shell.

Beak sub-anterior, obtuse, prominent and arching over the hinge-line. Umbonal region gibbous, subtending an acute angle.

Anterior extremity short, acute, straight above, oblique below. Wing small, narrow-triangular, extending to a point below the middle of the length of the shell; margin concave; extremity acute, probably spiniform.

Test thin, marked by lamellose, often fasciculate striæ, which are more crowded on the anterior side and byssal depression, and more regular and distinct on the wing.

Interior unknown.

Three specimens of left valves have respectively the following dimensions: length 42, 40 and 36 mm., height 24, 27 and 24 mm., and hinge-line about 26, 24 and 24 mm.

This species differs from L. longispinum in the wider and somewhat less oblique body, with more regularly rounded posterior extremity: the sinus in the wing is less acute and farther below the cardinal line, also in the absence of the strong posterior spine of that species.

Formation and locality. In the Cheming group, near Elmira, N. Y.

LEPTODESMA ROBUSTUM.

PLATE XXI, FIGS 45, 46, 20; AND PLATE LXXXIX, FIG. 8

Leptodesma robustum, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 21, figs. 15, 16, 20, Jan., 1883.

Shell large, sub-rhomboidal: body obliquely ovate: length much greater than the height: ante-byssal margin rounded: straight below, or scarcely impressed by the sinus, making a broad curve around the base to the postbasal extremity and thence abruptly recurving toward the beak.

Left valve gibbous above, regularly convex below the middle; the greatest convexity about one-third the length of the valve from the beak. Right valve moderately convex in the middle, flat below and scarcely gibbons on the umbo.

Hinge-line straight, about equal to the length of the shell.

Beaks nearly anterior, obtuse, sub-crect, very prominent, rising above the hinge-line. Umbonal region gibbous, prominent, abruptly elevated along the post-umbonal side for more than half the length of the shell, then merged in the general convexity; on the anterior side obscurely limited by a broad undefined depression. Umbonal angle acute.

Anterior extremity searcely auriculate. Wing small, narrow-triangular, extending about half the length of the valve, defined by the curving of the striæ; margin strongly concave, the deepest concavity just below the hinge; cardinal margin thickened and extended into a strong spine. In the right valve the wing is larger and broader, and the sinus less deep; the anterior extremity corresponds with that of the left valve.

Test moderately thick, marked by fine concentric striæ which become

more numerous and fasciculate at irregular intervals, producing a slightly undulated surface, crowded and lamellose on the anterior.

Interior unknown.

A specimen of a left valve has a length, from beak to base, of 43 mm., height 29 mm., and hinge-line to the base of the spine 25 mm. A right valve, referred to this species, has a length of 32 mm., height 27 mm., and hinge-line, exclusive of the spine, 31 mm.

This species is larger and more robust than L. longispinum; the body is wider, less oblique, and less abruptly recurving at the post-basal extremity; the wing is larger and the greatest depth of the sinus not quite so near the cardinal line; the strice do not recurve so abruptly forward on the posterior slope; the right valve is proportionally higher; the wing is less deeply sinuate, and the spiniform extension is shorter.

Compared with L. Mortoni, the body of the shell is less oblique and more expanded, while the wing is much smaller and the sinus nearer the hinge-line.

Formation and locality. In the middle portion of the Cheming group at Painted Post, Steuben county, N. Y.

Leptodesma Agassizi, n. sp.

PLATE LXXXIX, FIGS. 17-19

SHELL of medium size, sub-rhomboidal; body broadly ovate, oblique to the hinge-line at an angle of from 50° to 55°; length nearly one-third greater than the height; anterior margin broadly rounded below the byssal sinus; ventral margin regularly curved; more abruptly curved at the post-basal extremity.

Left valve moderately convex below, more convex above and gibbous on the umbo. Right valve less convex.

Hinge-line straight, about equal to the height of the valve.

Beaks sub-anterior, scarcely directed forward, prominent, rising a little above the hinge-line. Umbonal region moderately gibbons, subtending an acute angle.

Anterior end large, obtuse, truncate above and curving below into the

byssal sinus, limited by an oblique depression which reaches to near the middle of the length of the valve. Wing small, joining the body below the middle; margin oblique below and abruptly concave just beneath the cardinal line, recurving and produced into a short spiniform extension. The right valve is less convex, the wing larger and more extended along the posterior slope.

Test thin, marked by fine, distant, lamellose striæ with intermediate finer lines. The stronger striæ are more conspicuous on the anterior. The partial easts are nearly smooth.

Interior unknown.

One specimen has a length of 29 mm., height 23 mm., hinge, to base of spine, 15 mm. Another example has a length of 26 mm., height 19 mm., hinge, to base of spine, 15 mm.

This species bears a general resemblance to *L. spinigerum*, with which it is sometimes associated, but the body is more erect and much wider below; the wing is somewhat wider, the spine shorter, and the strice less strongly marked.

Formation and locality. In the middle portion of the Chemung group, on the Chemung river, between Elmira and Waverly, N. Y.

LEPTODESMA PROTEXTUM.

PLATE XXI, FIGS 22, 23

Avicula protexta, Conrad. Jour. Acad. Nat. Sci., Phila., vol. viii, p. 238, pl. 12, fig. 6, 1842.

Pterinea protexta (Conrad), S. A. Miller. Cat. Amer. Pal. Foss., p. 202. 1877.

Leptodesma protextum (Conrad), Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 21, figs. 22, 23. Jan., 1883.

Shell small, sub-rhomboidal; body elongate-ovate, very oblique; length nearly twice as great as the height; anterior margin below the byssal sinus, oblique; base broadly rounded and abruptly recurved on the post-basal extremity.

Valves sub-equally convex: the greatest convexity is above the middle of the length, becoming less toward the posterior side, which is somewhat depressed. The right valve is apparently a little smaller than the left.

Hinge-line straight, about equal to the length of the shell.

Beaks near the anterior end of the valve obtuse, rounded, prominent, inclined forward. Umbonal region narrow, gibbous for a short space below the hinge, subtending an acute angle.

Anterior end scarcely anriculate, abruptly rounded in the left valve, pointed in the right valve, limited by a broad, undefined depression, which is less marked in the right valve. Byssal sinus shallow. Wing narrow-triangular, joining the body near the posterior extremity of the valve, defined by the direction of the striæ; margin deeply concave, the greatest concavity just beneath the hinge-line; extremity produced into a sharp spine which extends nearly as far as the posterior margin of the shell.

Test thin, marked by concentric striae of growth, which are crowded into fascicles at irregular intervals, giving a somewhat wrinkled or undulating surface. On the anterior side the striae are crowded and lamellose, while they are quite regular and closely arranged over the wing. On the external shell the striae are elevated into regular, equidistant lamellæ. In the exfoliated shell, or partial casts, the surface presents obscure or obsolescent radii which appear to belong to the intimate shell-structure, and which are not shown on well-preserved specimens.

Interior unknown.

The largest specimen observed has a length of 26 mm, height 13 mm, hinge-line 20 mm. A similar right valve has a length of 23 mm, height 10 mm, hinge-line 16 mm. The specimens are usually smaller than those figured.

This species, in form of body and in the concentric striæ, resembles L. longispinum; but the anterior extremity (especially in the right valve) is narrower, the wing is extended farther down the body of the valve, and the spine is less produced.

This shell in its usual condition of preservation (that is, having the spiniform process of the wing broken off, or the wing partially covered) presents the characters described by Mr. Conrad, although not illustrated in his figure. A specimen of this species is labelled in the hand writing of Mr. Conrad, Avicula protesta, and therefore the name is retained.

Formation and localities. In the Chemung group at Chemung Narrows, N. Y., and Tioga county, Pa.

LEPTODESMA BECKI.

PLATE XXII, FIG., 3-5.

Leptodesma Becki, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations; Pl. 22, figs. 3-5 (and figs. 6 and 7 in error). Jan., 1883.

Shell of medium size, sub-rhomboidal; body oblique, narrowly ovate in the left valve; length more than one-third greater than the height; anterior margin oblique, extending in nearly a direct line into the broadly rounded basal margin; post-basal margin produced, not abruptly recurved into the wing.

Left valve gibbous except in the lower part. Right valve less convex.

Hinge-line straight, less than the length of the shell, and greater than the height.

Beaks at about the anterior third of the hinge-line, obtuse, directed forward and arching over the hinge. Umbonal region gibbous, scarcely defined anteriorly, but well-marked posteriorly by the abrupt slope of the side. Umbonal angle acute.

Anterior end truncate, acute at the extremity. Wing of medium size, not distinctly limited, joining the body nearly at the posterior extremity; margin concave; extremity produced into a short spine. The right valve is proportionally higher, the body less distinctly defined, and the wing larger.

Test thin, marked by concentric striæ, which are crowded and somewhat lamellose in front, and closely and evenly arranged on the wing. The hingeline has a single narrow groove.

A left valve has a length of 28 mm., height 17 mm., hinge-line about 22 mm. A detached right valve has a length of 29 mm., height 20 mm., hinge-line 30 mm.

This species resembles *L. robustum* in general expression and in the sinus of the wing, but the body is narrower, more regularly convex, the base less expanded,

and the basal margin and the strice along the posterior slope are not so abruptly recurved.

Formation and localities. In the Chemung group, near Corning, Chemung county, and Portville, Alleghany county, N. Y.

LEPTODESMA DISPARILE.

PLATE XXV, FIGS 2-4; AND PLATE LXXXIX, FIGS, 23, 24

Leplodesma disparile, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 25, figs. 2-4. Jan., 1883.

Shell of small or medium size, sub-rhomboidal; body ovate, oblique to the hinge at about 45°; length more than one-third greater than the height in the left valve; ante-byssal margin oblique, gently curving into the sinus; basal and posterior margins regularly rounded.

Left valve convex below, gibbous above. Right valve flat or concave below, depressed-convex in the middle, and gibbous on the umbo.

Hinge-line straight, greater than the length of the shell.

Beak sub-anterior, prominent, rising above the hinge-line, directed slightly forward. Umbonal region gibbous, subtending an acute angle.

Anterior end large, somewhat produced, limited by a nearly vertical byssal depression; extremity obtusely angular. Wing somewhat large, joining the body near the posterior extremity; margin oblique below, concave above the middle, and produced into an elongate spiniform process. The right valve is smaller, the wing more extended and less defined, while the anterior end is large and well defined by the byssal sinns and sulcus.

Test marked by concentric, lamellose ridges with intermediate finer lines of growth: the lamellæ are sometimes more distinct on the right valve.

Interior unknown.

A left valve has a length of 28 mm., height 20 mm., hinge-line more than 30 mm. A right valve has a length of 30 mm., height 18 mm., hinge-line 33 mm.

This species is distinguished from *L. Rogersi* and *L. spinigerum* by the large anterior end, narrower umbo, more extended wing, with less deeply sinuate margin, less convex right valve, and the regular concentric lamellose ridges of the surface.

Formation and localities. In sandstones of the Upper Chemung group, McKean county, Pa.: and Farmer's Valley, Cattaraugus county, N. Y.

LEPTODESMA SOCIALE.

PLATE XXI, FIGS, 24-28 (33, 34?).

Leptodesma sociale, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 21, figs. 24-28 (33, 34!).
Jan., 1883.

Shell small, sub-rhomboidal; body broad-ovate, oblique; length greater than the height; anterior margin nearly straight and quite oblique; base regularly rounded; post-basal side somewhat extended and abruptly recurved.

Left valve convex, gibbous in the upper part, more convex than the right valve, which is moderately convex above and depressed-convex or flat below.

Hinge-line straight, sometimes greater than the length of the shell.

Beaks at about the anterior third of the hinge-line; the left beak prominent, obtuse; the right beak less conspicuous. Umbonal angle acute.

Anterior extremity sub-anriculate, straight above, slightly extended. Wing triangular, joining the body of the valve below the middle of its length (measured from hinge to base): margin regularly concave: extremity produced into a spine, which, in perfect specimens, reaches beyond the margin of the valve. In the right valve the wing is less distinctly defined, and the sinus not so deeply concave.

Surface marked by fine concentric striæ, which at somewhat regular intervals are elevated into sharp, conspicuous lamellæ, or sometimes into fascicles of striæ producing elevations. These become crowded and irregular on the anterior of the valve, and are very regular and uniform on the wing and on the right valve.

Interior unknown.

A specimen of a left valve has a length of 10 mm., height 7.5 mm., hingeline about 10 mm. A similar specimen has a length of 11 mm., height 6.5 mm., and hinge-line about 11 mm. A right valve has a length of 9 mm., height 6 mm., hinge-line about 8 mm. Another one has a length of 16 mm., height 11 mm., hinge-line about 16 mm.

This is a small and abundant species, often occurring in great numbers on the surfaces of shaly layers. It is distinguished by its form and the regular lamellose appearance of the surface.

Formation and localities. In the shales of the Cheming group at Connewango, Cattaraugus county: Nanticoke Springs, Broome county, and south of Ithaca, N. Y.

LEPTODESMA POTENS.

PLATE XM, FIGS 21, 30; PLATE XXII, FIGS, 11, 12, 19, (20?) 21; AND PLATE LXXXIX, FIG. 7.

Leptodesma potens, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 21, figs. 21, 30; pl. 22, figs. 11, 12, 19, 21. Jan., 1883.

Shell large, sub-rhomboidal; body ovate, oblique, broad below; length more than one-third greater than the height; ante-byssal margin sub-truncate, erect, oblique below; basal margin broadly curving; posterior margin broad, extended and abruptly recurving at the upper extremity.

Left valve convex, gibbous above: the greatest convexity at one-third the height of the shell from the beak. Right valve almost equally convex, more abruptly gibbous on the umbo, and comparatively shorter and wider.

Hinge-line straight, about equal to the length of the shell.

Beak sub-anterior, obtuse, erect, prominent, arching over the hinge. Umbonal region gibbous, very prominent, limited anteriorly by a shallow depression extending from a point anterior to the beak to the margin at one-third the height of the shell below the hinge-line; posteriorly limited by the abrupt post-cardinal slope. Umbonal angle acute.

Anterior extremity extended and angular. Wing large, triangular, joining the body near the posterior extremity, distinctly limited; margin broadly sinuate; extremity produced into a strong spine (the extent of which is unknown).

Surface marked by strong concentric lines of growth, which are crowded into small fascicles at irregular intervals on the body of the shell, and become lamellose expansions on the anterior. On the wing they appear as sharp equidistant lamellae. Casts of the interior show the concentric striae in a subdued condition.

Interior unknown.

The largest left valve observed has a length, measured from beak to base, of 62 mm., height 46 mm., hinge-line, exclusive of the spine, 58 mm. A smaller specimen has a length of 57 mm., height 39 mm., hinge-line, to base of spine, 58 mm. A right valve referred to this species has a length of 36 mm., height 28 mm., and hinge-line, to base of spine, 35 mm.

This species more nearly resembles L. robustum than any of the forms here described; but it is larger, the wing proportionally larger and distinctly limited, and the sinus of the wing more central. The right valve is also more convex and the wing more deeply sinuate. It occurs in the upper members of the Chemung group, associated with Spirifera Verueuili, while L. robustum is found only in the middle of the series.

It is a larger and more robust shell than L. Mortoni, and the right valves are very unlike.

Formation and localities. In the Upper Chemung group at Olean, Portville, Cassadaga lake, and in loose specimens collected near Panama, N. Y.

LEPTODESMA POTENS. Var. JUVENS.

PLATE XXII, FIG. 16.

Leptodesma potens, var. jurens, Hall. Pal. N. V., vol. v, pt, 1. Plates and Explanations: Pl. 22, fig. 16. Jan., 1883.

Shell small, rhomboidal: body ovate, oblique; the greatest length more than once and a half the height; anterior margin oblique, very broadly curving below: post-basal extremity rounded and abruptly recurved.

Left valve convex below, very gibbous and ventricose in the middle and above. Right valve unknown.

Hinge-line straight, less than the length of the shell.

Beak obtuse, situated at the anterior third of the hinge-line, prominent, arching over the hinge-line and inclined slightly forward. Umbonal region ventricose, obscurely limited anteriorly by an undefined depression, and on the posterior side by the abrupt and almost vertical post-umbonal slope. Umbonal angle acute.

Anterior end short, triangular; extremity acute. Wing broad-triangular, joining the body of the shell near the posterior end; margin regularly concave; extremity acute.

Test thin, marked by extremely fine, regular concentric striæ, which are crowded into fascicles on the anterior end.

Interior unknown.

The specimen described has a greatest length of 25 mm., height 15 mm., hinge-line 22 mm.

This shell resembles L. potens, but it is apparently more extended and acute in front, sub-truncate on the posterior end; the wing joins the body near the posterior extremity, and its margin is less deeply sinuate than L. potens. These variations appear in comparison with the older individuals of that species and cannot be taken as positive evidence of specific difference, while at the same time their common characters may be insufficient to unite them.

Formation and locality. In the Chemung group at East Randolph, Cattaraugus county, N. Y.

LEPTODESMA MORTONI.

PLATE XXI, FIGS, 29, 31, 32; AND PLATE LXXXIX, FIGS, 9-11.

Leptodesma Mortoni, Ball. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 21, figs. 29, 31, 32 (pl. 22, fig. 20 in error), Jan., 1883.

Shell above the medium size, sub-rhomboidal; body elongate sub-ovate, very oblique; length more than one-half greater than the height; ventral margin broadly curving to the base; the posterior margin extended and abruptly recurved.

Left valve convex, gibbous above. Right valve depressed-convex below, and abruptly gibbous at the umbo.

Hinge-line straight; length less than the length of the shell.

Beaks sub-anterior, obtuse, erect, prominent, arching over the cardinal line. Umbonal region gibbous and gradually sloping down to the general convexity, abruptly limited on the posterior side, subtending an acute angle.

Anterior end extended, acute and nasute. Wing large, triangular, slightly convex, joining the body of the shell more than two-thirds of the length below the beak; margin symmetrically concave; extremity produced and very acute. In the right valve the anterior end is broad and flat; the wing is large, with no defined limit between it and the body of the valve.

Surface marked by elevated concentric striæ which, at irregular intervals are fasciculate, producing undulations on the surface. This character is often marked on the front of the shell where the fascicles are composed of three or four distinct striæ.

Interior unknown.

A specimen of the left valve has a length, measured from beak to base, of 44 mm., height 30 mm., hinge-line about 38 mm. Another example has a length of 45 mm., height 25 mm., hinge-line 32 mm. A right valve measures 43 mm. in extreme length, height 30 mm., hinge-line about 34 mm.

This species bears some resemblance to *L. robustum*, but the body is more oblique and not so broad below; the anterior extremity is acute; the wing larger, more extended along the valve and very symmetrically concave on the margin. The form of the shell is very similar to *L. longispinum*, but differs by its larger wing, the broader sinus and more regularly rounded posterior extremity, and in the latter respect it resembles *L. Shumardi*, while it is otherwise very different.

Formation and localities. In the Chemung group at Portville and Little Genesee, Alleghany county, N. Y.

Leptodesma Billingsi, n. sp.

PLATE LXXXIX, FIGS 12-45.

Shell large, sub-rhomboidal; body elongate-ovate, or sub-cylindrical, very oblique; length about twice the height; ante-byssal margin rounded, becoming straight or slightly concave at the sinus; ventral margin broadly curving; posterior margin extended, acutely recurved at the post-basal extremity.

Left valve gibbons on the umbo, convex below. Right valve unknown. Hinge-line straight; length, including the spine, nearly equal to the length of the valve.

Beak sub-anterior, obtuse, slightly oblique, prominent. Umbonal region somewhat gibbous, subtending an acute angle.

Anterior end limited by a shallow byssal depression, acute and nasute at the extremity. Wing long, narrow-triangular, extending below the middle of the valve; margin sinuate; extremity produced into a spine.

Test thin, marked by fine concentric strike which are abruptly arched on the posterior slope, regular upon the wing, and crowded into fine irregular fascicles which are conspicuous on the anterior. Some specimens show sharp, elevated, lamellose strike at equal distances on the surface of the body. The surface characters vary with the different states of exfoliation and maceration.

The largest specimen observed has a greatest length, from beak to base, of 57 mm., height 36 mm., hinge-line, to base of spine, 35 mm. A small example of the left valve has a length of 34 mm., height 18 mm., and hinge-line about 35 mm.

This species is more elongate and oblique than L. longispinum, the wing extends farther down along the posterior slope, and the anterior extremity is fuller and more acute.

Formation and localities. In the Chemung group at Panama, N. Y. Other specimens from near Elmira, N. Y., and Mansfield, Tioga county, Pa., are referred to this species with reservation.

LEPTODESMA MATHERI.

PLATE XXII, FIGS. 8, 9, 10; AND PLATE LXXXIX, FIG. 25.

Leptodesma Matheri, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 22, figs. 8-10, Jan., 1883.

Shell of medium size, rhomboidal; body ovate, oblique at an angle of 45° with the hinge-line; length about one-half greater than the height; ante-byssal margin vertical in front, joining the broad curvature of the basal margin; posterior margin produced and abruptly recurved.

Left valve moderately convex below, scarcely gibbous above. Right valve shorter and less convex.

Hinge-line straight; length much less than the length of the valve, but nearly equal to the height.

Beaks at about the anterior third of the hinge, obtuse, directed slightly forward, not very prominent. Umbonal region moderately gibbous, subtending an acute angle.

Anterior end produced, flattened, acute at the extremity. Wing of moderate dimensions, extending nearly to the posterior extremity; margin gently concave; extremity produced and acute.

Test thin, marked by fine concentric strie which are fasciculate on the body of the shell, producing an undulated appearance. The strie are sub-lamellose on the anterior and regular over the wing.

Interior unknown.

A left valve has a length of 35 mm., height 23 mm., and hinge-line about 28 mm. A similar right valve has a length of 29 mm., and height 20 mm.

This species differs from *L. robustum* in its comparatively larger wing, without distinct sinus in the margin, and the more produced anterior end. It resembles *L. potens*, but differs in its more produced anterior end. less gibbous body, and more abruptly recurved posterior margin.

Formation and locality. In the upper beds of the Chemung group, near Bradford, McKean county, Pa.

Leptodesma Stephani, n. sp.

PLATE LXXXIX, FIGS, 20-22

Shell above the medium size, sub-rhomboidal; body ovate, straight on the post-umbonal slope, oblique at an angle of from 30° to 40° with the hinge-line; height about five-eighths of the length; ante-byssal margin vertically truncate above, curving below into the sinus; basal margin broadly rounded, abruptly recurved at the post-basal extremity.

Left valve convex, somewhat gibbons above. Right valve depressedconvex below and abruptly gibbons at the umbo.

Hinge-line straight, equal to about five-sixths the length of the valve.

Beaks sub-anterior, directed slightly forward, obtuse, prominent, rising a little above the cardinal line. Umbonal region regularly gibbous, subtending an acute angle.

Anterior end large, short, defined by a nearly vertical byssal depression, which reaches the margin about one-third the length of the valve from the anterior extremity, which is abruptly rounded or truncate. Wing joining the body at less than one-fourth the length of the valve from the posterior extremity; margin very oblique below, deeply concave above; the greatest depth of the concavity is above the middle, whence the margin is abruptly recurved and produced into a spiniform extension.

Test of moderate thickness, marked by nearly equidistant lamellose concentric striæ, with intermediate finer striæ of growth. The lamellose striæ are subdued upon the wing, and very strong and irregular on the anterior side.

Interior unknown.

A large specimen of this species has a length of 43 mm., height 25 mm., and hinge-line about 33 mm. A somewhat smaller example has a length of 37 mm., height 25 mm., and hinge-line 30 mm. A right valve measures 33 mm. in length, 24 mm. in height, and hinge-line 28 mm.

This species resembles L. Matheri, with which it is associated, but differs in its greater obliquity, more elongate outline, more extended and flatter wing,

which is more deeply concave on the margin and with the extremity more produced; the anterior extremity is also larger and apparently not produced. The right valves of the two species are very unlike.

Formation and localities. In the Upper Chemung group at Bradford, Pa., and doubtfully occurring near Elmira, N. Y.

LEPTODESMA LEPIDUM.

PLATE XXI, FIG. 40; AND PLATE LXXXIX, FIG. 16.

Leptodesma lepidum, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 21, fig. 40. Jan., 1883.

Shell of medium size, narrow, sub-rhomboidal; body narrowly ovate, somewhat straight on the posterior slope, oblique at an angle of about 35° with the hinge-line; length less than twice the height; margin very oblique anteriorly, curving into a marked byssal sinus; base broadly rounded to the posterior extremity, which is abruptly recurved.

Left valve regularly convex below, gibbous above. Right valve very depressed-convex, nearly flat below, moderately convex on the umbo, considerably smaller than the left.

Hinge-line straight; length more than two-thirds the greatest length of the shell.

Beaks sub-anterior, directed forward, prominent in the left valve, depressed in the right valve. Umbonal region narrow and abruptly gibbous in the left valve; depressed and scarcely defined in the right. Umbonal angle about 30°.

Anterior end small, acute at the extremity, limited by a distinct vertical byssal depression. Wing narrow-triangular, joining the body at about one-fourth the length from the posterior extremity: margin deeply concave, abruptly recurved along the cardinal line, and extended into a spiniform process. In the right valve the wing is scarcely defined.

Test marked by very fine concentric striæ, which are regular upon the body and wing, and crowded and fasciculate on the anterior. In the right valve the striæ are more distant and more even in their character.

Interior unknown.

A left valve of medium size has a length of 41 mm., height 22 mm., length of cardinal line about 35 mm.

This species differs from L. Hector in its greater obliquity, broader body below, more produced and abruptly recurved post-basal extremity, deeper and broader byssal depression, more produced anterior end, and narrower and more deeply sinuate wing, with a more extended extremity.

Formation and localities. In the central portion of the Cheming group at Philipsburg, Alleghany county, N. Y., and below the conglomerate (same position) in Sullivan township, Tioga county, Pa.

LEPTODESMA CURVATUM.

PLATE XXV, FIG. 5.

Leptodesma curvatum, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations; Pl 25, fig. 5. Jan., 1883.

Shell above the medium size, rhomboidal; body ovate, sub-arcuate above, oblique at an angle of nearly 30° with the hinge-line; length and height as 7 to 4; ante-byssal margin oblique above, curving into a long, shallow sinus; basal and posterior margins forming a broad, continuous curve, and abruptly recurving at the post-basal extremity.

Left valve regularly convex below, gibbous above the middle. Right valve unknown.

Hinge-line straight; length about equal to the length of the valve, but not fully seen, as the spiniform termination is imperfect.

Beak sub-anterior, prominent, directed forward. Umbonal region gibbons, subtending an acute angle.

Anterior end large, abruptly acute at the extremity, limited by a distinct, nearly vertical bysal depression. Wing narrow-triangular, joining the body at the posterior extremity; margin very oblique below, concave above, abruptly recurved just below the cardinal line and extended into a spiniform process. In a cast of the left valve the wing is distinctly separated from the body by a marked furrow.

Test moderately thick, marked by elevated lamellose striæ, with finer intermediate lines.

Interior unknown.

The specimen described has a length of 42 mm, height 24 mm, hingeline, to base of spine, 30 mm. The spine is probably extended from 5 to 10 mm, beyond.

This species resembles L, lepidum, but differs in its more gibbous form, larger and more obtuse anterior extremity.

Formation and locality. In sandstones of the Upper Chemung group, McKean county, Pa., on the road from Bradford to Farmers' Valley, Cattaraugus county, N. Y.

Section b, umbonata.

LEPTODESMA MEDON, n. sp.

PLATE XC, FIGS, 1-4.

Shell of medium size, sub-rhomboidal; body broad-ovate, oblique at an angle of about 60° with the hinge-line; length nearly one-third greater than the height; ante-byssal margin curving slightly outward, concave at the sinus; basal and posterior margins broadly rounded, passing directly into the wing.

Left valve gibbous above, depressed-convex below. Right valve somewhat less convex than the left. The right valve appears to have been somewhat smaller and the base more extended than in the left valve.

Hinge-line straight; length a little greater than the height of the shell.

Beaks at about the anterior third of the hinge, acute, prominent, arching over the hinge-line. Umbonal region gibbous, descending almost vertically on the posterior, and sloping abruptly on the anterior side. Umbonal angle acute.

Anterior end short, separated from the body by a marked sinus: extremity angular, gently rounded below. Wing not defined, broad-triangular, reaching nearly to the posterior end of the body; margin slightly concave; extremity acute.

Test thin, marked by concentric striæ, which, on the body of the shell, are crowded into fascieles and assume a distinct regularity in passing over the wing. The hinge shows one or two slender parallel grooves.

Three similar specimens of the left have respectively the following dimensions: length 32, 32 and 33 mm., height 22, 25 and 23 mm., and hinge-line 25, 27 and 25 mm.

In this species the body of the shell resembles L. robustum and L. potens, but is less oblique to the hinge-line, the wing less defined, and its posterior extremity not produced into a spine.

Formation and locality. In the upper part of the Chemung group, Lawrence-ville, Tioga county, Pa.

LEPTODESMA UMBONATUM.

PLATE XXII, FIG. 13; AND PLATE XC, FIG. 9.

Loptodesma umbonatum, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 22, fig. 13, Jan., 1883.

Shell of medium size, rhomboidal; body oblique, narrowly ovate; greatest length one-half more than the height; ante-byssal margin straight or slightly convex, enrying into the wide sinus, oblique below; ventral margin broadly rounded; posterior extremity moderately produced, abruptly recurved.

Left valve convex, ventricose above the lower third. Right valve unknown.

Hinge-line straight; length less than the length of the shell.

Beak at about the anterior third of the cardinal line, directed slightly forward, prominent and arching over the hinge. Umbonal region narrow, and ventricose, defined anteriorly by a broad, shallow depression, which is nearly vertical to the hinge-line, and posteriorly by the abrupt depression of the body.

Anterior end acute, triangular. Wing rather large, triangular, convex, joining the body of the shell near the posterior extremity; margin broadly coneave; extremity produced, acute.

Test thin, marked by fine concentric lines of growth which are irregularly crowded into small fascicles, producing a slightly undulated appearance. The strice are strong and regular over the wing.

Interior unknown.

The left valve described has a length of 41 mm., height 27 mm., hinge-line about 38 mm.

This species bears some general resemblance to *L. potens* and *L. robustum*, but the body is narrower, less oblique and much more gibbous, the beak more elevated, and the posterior extremity of the body less expanded. The wing is also much larger than in *L. robustum*. It is very closely allied to *L. umbonatum* var. *depressum*, Pl. xxii, fig. 14., but differs in its smaller mucronate anterior end; the body is more convex and narrower below, and the extremity of the wing more produced.

Formation and locality. In a calcareous band of the upper part of the Chemung group, Twenty-mile creek, Chautauqua county, N. Y.

Leptodesma umbonatum, var. depressum.

PLATE XXII, FIG. 14; AND PLATE XC, FIG. 10.

Leptodesma umbonatum, var. depressum, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations; Pl. 22, fig. 14. Jan., 1883.

Shell of medium size, rhomboidal: body very oblique-ovate: length once and a half greater than the height; ante-byssal margin, below the acute extremity, regularly curving into the ventral margin: posterior extremity produced, with the margin gently recurving into the wing.

Left valve convex below, gibbous above. Right valve smaller, a little less convex, abruptly gibbous on the umbo.

Hinge-line straight, somewhat less than the greatest length of the shell.

Beaks sub-anterior, obtuse, directed slightly forward, very prominent, arching over the hinge-line.

Anterior end short, large, limited by a broad, undefined depression: extremity produced, acute. Wing large, triangular, not distinctly defined,

joining the body near the posterior end; extremity produced, acute, and probably extended into a short spine.

Test marked by fine striae of growth which are irregularly fasciculate, producing a slight undulation of the surface. The striae are lamellose on the anterior side and regular on the wing.

Interior unknown.

The specimen described has a greatest length of about 40 mm., height 25 mm., and hinge-line 35 mm.

This form differs from L. umbonatum in the lesser convexity and greater width of the lower part of the body; less abrupt depression on the anterior side from the nmbo; the posterior slope less elevated and defined below the middle, and a much larger ante-byssal portion of the shell.

Formation and locality. In the upper part of the Chemung group, Napoli Centre, Cattaraugus county, N. Y.

LEPTODESMA NAVIFORME.

PLATE XXII, FIG. 15; AND PLATE XXIII, FIG. 1.

Leptodesma naviforme, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 22, fig. 15; pl. 23, fig. 1. Jan., 1883.

Shell below the medium size, rhomboidal; body very oblique, short-ovate; length more than one-third greater than the height; anterior extremity subtruncate; margin curving to the broadly rounded base; posterior margin slightly produced, gently curving forward, nearly vertical.

Left valve convex below, very gibbous above the middle. Right valve depressed-convex below, gibbous above.

Hinge-line straight, more than one-third greater than the height of the shell.

Beaks obtuse, situated at the anterior fourth of the hinge-line, prominent, directed slightly forward. Umbonal region gibbous, sloping abruptly into the wing.

Anterior end short, acute. Wing large, not distinctly limited, extending almost to the posterior extremity; margin scarcely concave below; extremity produced, acute.

Test marked by fine concentric striæ, which are crowded into fascicles at nearly equal intervals, rounded upon the upper part of the body, and sub-angular on the lower part. The striæ are crowded and lamellose on the anterior; on the posterior slope they make a short abrupt curve, passing over the wing with a gently forward direction and curving backward just below the hingeline. In the weathered surface of the right valve the concentric undulations are stronger, the post-cardinal slope is marked by strong interrupted radii which appear to belong to the intimate structure of the shell. The hinge is marked by a single narrow groove.

A specimen of the left valve has a length of 22 mm., height 14 mm., and hinge-line about 21 mm. A right valve occurring in the same association has a length, from beak to base, of 26 mm., height 18 mm., and hinge-line about 25 mm.

This species is quite unlike any here described.

Formation and locality. In the lower beds of the Chemung group at the Inclined Plane, near Ithaca, N. Y.

Leptodesma Cadmus, n. sp.

PLATE XC, FIGS, 6, 7.

Shell of medium size, rhomboidal; body oblique, narrowly ovate or subcylindrical: length nearly one-third greater than the height: ante-byssal margin somewhat vertically truncate, sloping below into the broadly curving base; posterior margin abruptly curved.

Valves convex, gibbous above; the right valve smaller than the left.

Hinge-line straight, nearly equal to the height of the shell.

Beaks at about the anterior third of the hinge-line acute, directed forward, prominent, arching over the cardinal line. Umbonal region abruptly gibbous, subtending an acute angle.

Anterior end small, terminating in a narrow nasute extension. Wing comparatively large, triangular, joining the body near the posterior end; surface concave: margin gently sinuate; extremity produced into a short spiniform extension.

Test thin, marked by fine concentric striæ, which are somewhat regularly fasciculate on the body of the shell, crowded and sub-lamellose on the anterior, and regular over the wing, curving backward just below the hinge, indicating a spiniform extension of the wing. On the body of the right valve the striæ form sharp, lamellose elevations at somewhat equal intervals.

The hinge is marked by one or two narrow, longitudinal grooves.

A left valve has a length of 34 mm., height 24 mm., and hinge-line 22 mm. A similar specimen, somewhat vertically compressed, has a length of 36 mm., height 24 mm., hinge-line 25 mm.

This species resembles L, umbonatum var. depressum, but differs in its smaller and narrower anterior end and more cylindrical body, and wing without a broad sinus in the margin.

Formation and localities. In the upper beds of the Chemung group, Steuben county, N. Y., and Tioga and Bradford counties, Pa.

Leptodesma Creon, n. sp.

PLATE XC, FIGS. 11-13.

Shell below medium size, sub-rhomboidal; body ovate, oblique to the hingeline at an angle of about 55°; length nearly one-third greater than the height; ante-byssal margin slightly oblique or rounded, distinctly sinuate below, then gently curving to the broad base; posterior margin broad, joining the wing without interruption.

Left valve convex below, gibbous above. Right valve less gibbous than the left and more expanded.

Hinge-line straight; length a little greater than the height of the shell.

Beaks at about the anterior third of the hinge-line, sub-acute, directed forward, prominent, arching over the hinge. Umbonal region very gibbous,

narrow, limited by the abrupt slope of the posterior side. Umbonal angle acute.

Anterior end large, short, rounded, curving into the byssal sinus, defined by a marked byssal depression; extremity acute. Byssal sinus marked by a broad, shallow curvature of the margin. Wing small, narrow-triangular, not distinctly limited; margin concave; extremity acute. The wing of the right valve is comparatively larger.

Test thin, marked by fine concentric lines of growth, which are sometimes regular or often crowded into fascieles on the body of the shell.

Cardinal line marked by a narrow longitudinal groove. Interior unknown.

A left valve has a length of 32 mm, height 21 mm, hinge-line 23 mm. A smaller specimen has a length of 29 mm, height 20 mm, hinge-line 22 mm.

This species resembles in general expression *L. umbonatum var. depressum*, but it is uniformly smaller, the anterior end shorter, byssal depression narrower, wing smaller, the recurving of the posterior margin of the body less abrupt, the limits of the wing less distinctly marked, the extremity less produced, and the umbonal region not so abruptly gibbous.

Formation and locality. In the upper part of the Chemung group, Lawrence-ville, Tioga county, Pa.

Leptodesma Demus, n. sp.

PLATE XC, FIGS 15, 16.

Shell of medium size, rhomboidal; body very oblique, narrowly ovate; extreme length more than one-third greater than the height; ante-byssal margin oblique, rounded below, concave at the sinus; basal margin broadly rounded; posterior margin abruptly curved.

Left valve convex, gibbous above. Right valve of similar form, less convex, and in the posterior part wider and more depressed.

Hinge-line straight, about two-thirds as long as the length of the valve.

Beaks situated at about the anterior third of the hinge, prominent,

directed forward and rising a little above the cardinal line. Umbonal region gibbous, defined on the anterior by the byssal depression, and on the posterior by the slope of the side.

Anterior end large, limited by an oblique byssal depression, angular at the extremity and rounded below. Byssal sinus extending to a point more than one-third the height of the valve below the beak. Wing narrow-triangular, not distinctly limited: margin oblique, slightly convex, recurving just below the hinge-line; extremity angular.

Test marked by fine, irregular striæ, somewhat fasciculate on the body, and crowded and lamellose in front.

Interior unknown.

A well-preserved left valve has a length of 35 mm., height 20 mm., hingeline nearly 24 mm.

The body of the valve in this species is narrower and more elongate than in *L. Creon*, and the wing smaller and less distinctly defined. It resembles *L. Lichas*, but differs in its more gibbous umbo, stronger byssal depression, less oblique margin of wing, with less acute termination and proportionally shorter body.

Formation and locality. In sandstones of the Chemiung group at Lawrence-ville, Tioga county, Pa.

Leptodesma Loxias, n. sp.

PLATE XC, FIG. 14.

Suell of medium size, rhomboidal; body ovate, narrow above, oblique to the hinge-line at an angle of about 40°; height one-third less than the length; ante-byssal margin oblique, rounding into the sinus; ventral margin broadly rounded; posterior margin abruptly recurved.

Left valve convex, gibbous in the middle and above. Right valve unknown.

Hinge-line straight, greater than the height of the shell.

Beak obtuse, prominent, arching over the cardinal line, situated at the

anterior third of the hinge. Umbonal region narrow and gibbous, subtending an acute angle.

Anterior end limited by a broad, nearly vertical byssal depression which extends one-half the height of the valve; margin convex; extremity acuminate. Wing triangular, not distinctly limited, joining the body near the posterior extremity; margin oblique, nearly straight, concave just beneath the hinge-line; extremity mucronate.

Test thin, marked by fine concentric striæ, which are regular over the body and wing and strongly lamellose and fasciculate on the anterior end.

luterior unknown.

A small left valve has a greatest length of 28 mm., height 17 mm., hingeline 21 mm.

This species is distinguished from L. Creon and L. Demus by its narrower anterior end and more rounded ventral margin.

Formation and locality. In the Chemung group, Lawrenceville, Tioga county, Pa.

LEPTODESMA MENTOR, n. sp.

PLATE XC, FIG. 5; AND PLATE XXIII, FIG. 15?

Shell of medium size, sub-rhomboidal; body elongate-ovate, narrow at the anterior end, oblique, making an angle of about 40° with the hinge-line; length one-third greater than the height; ante-byssal margin oblique, curving into the gently depressed sinus; basal margin broadly curving into the rounded posterior extremity.

Left valve moderately convex in the lower part, becoming convex in the middle and gibbous above. Right valve unknown.

Hinge-line straight: length about equal to the height of the valve.

Beak sub-anterior, directed forward, acute, but little elevated above the hinge-line. Umboual region abruptly, or sub-angularly gibbous, narrow, subtending an acute angle.

Anterior end small, narrow, limited by an oblique byssal depression which reaches about half way down the body of the shell: extremity pointed.

Wing joining the body near the post-extremity of the shell, defined by a shallow groove: margin oblique, straight, apparently slightly concave just below the eardinal line.

Test thin, leaving upon the cast the marks of the strice of growth which have been somewhat fascicled upon the body, giving it an obscurely undulated appearance.

Interior unknown.

A specimen of this species has a length of 35 mm., height 24 mm., and hinge-line nearly 24 mm.

This species resembles L. Orodes, but differs in its greater obliquity; the body is more attenuate toward the anterior, and the wing is distinctly limited.

This one, and several other species, have shown the presence of an alar furrow and obscure fold, similar to Ptychopteria.

Formation and locality. In a coarse sandstone of the Upper Cheming group, south of Smethport, McKean county, Pa.

LEPTODESMA ORODES.

PLATE XXV, FIGS. 6, 9, (10?); AND PLATE XC, FIG. 8.

Leptodesmu Orodes, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 25, figs. 6, 9 (101), Jan., 1883.

Shell of medium size, sub-rhomboidal; body ovate, oblique to the hinge-line at an angle of about 55°; length one-fifth greater than the height; ante-byssal margin a little oblique, nearly vertical above, eurving into a long, undefined sinus; ventral margin rounded into the broad posterior curve.

Left valve moderately convex in the lower part, increasing in convexity . to the middle of the length, where it becomes gibbous. Right valve unknown.

Hinge-line straight, a little less than the height of the valve.

Beak sub-anterior, directed forward, moderately prominent, scarcely rising above the cardinal line. Umbonal region abruptly gibbous, subtending an angle of about 30°.

Anterior end short in the direction of the hinge-line, separated from the body by a well-marked byssal depression extending for half the height of the valve: extremity abruptly angular. Wing large, joining the body below the middle of its length, obscurely defined from the body of the valve: margin moderately oblique, nearly straight, or slightly convex below, with a very gentle concavity just beneath the cardinal line.

Test thin; casts of the interior obscurely marked by fine strike of growth which are sometimes fasciculate upon the body of the shell.

Interior unknown.

An individual of medium size has a length of 32 mm., height 27 mm., and hinge-line 23 mm. A smaller example has a length of 25 mm., height 20 mm., and hinge-line 18 mm.

This species is distinguished from *L. Maclurii* by its shorter form, less parallel sides of the body, larger wing, which is not extended on the cardinal margin, and the body is not angular along its entire length.

The specimen, Pl. xxv, fig. 10, has been flattened by pressure and is referred with doubt to this species. It has the same general aspect, but is proportionally wider below the middle, and more broadly rounded on the post-basal margin, which peculiarities may have been produced by compression.

Formation and locality. In a coarse sandstone of the Upper Chemung group, on the road from Olean, N. Y., to Smethport, Pa.

Section c, rostrata.

LEPTODESMA EXTENUATUM.

PLATE XXII, FIG. 23; AND PLATE XC, FIGS. 17, 18.

Leptodesma extenuatum, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 22, fig. 23. Jan., 1883.

Shell of medium size, elongate, semi-ovate: body narrowly ovate and oblique to the hinge-line at an angle of about 30°; length nearly twice the height: ante-byssal margin very oblique, searcely depressed at the sinus, thence nearly straight to the broadly curved base: posterior margin abruptly recurved.

Left valve moderately convex below, gibbous on the umbo. Right valve flat below, depressed-convex in the middle, and more convex above, proportionally wider than the left, and distinguished by its depressed-convex form.

Hinge-line straight; length greater than the length of the valve.

Beak of left valve sub-anterior, acute, directed forward, rising slightly above the hinge-line. Beak of right valve depressed, not rising above the cardinal line. Umbonal region of left valve moderately gibbons, subtending a very acute angle.

Anterior end greatly extended, acute, rostrate, limited by a shallow byssal depression. Wing narrow-triangular, joining the body at the posterior extremity, defined by the recurving of the striæ; margin abruptly and symmetrically concave; extremity produced beyond the posterior limit of the shell.

Test thin, marked by fine, sharp, closely arranged, concentric striæ, which are sometimes fasciculate upon the body and anterior side, and very distinct upon the wing. Partial easts of the interior of the left valve give indications of fine radii which appear to belong to the intimate structure of the shell.

Characters of the interior unknown.

A left valve has a length of 32 mm., height 16 mm., and hinge-line 37 mm. A right valve has a length of 34 mm., height 19 mm., and hinge-line 40 mm.

This species is distinguished by the great length of the hinge-line, its narrow outline, and anterior extension. It approaches Pteroxites in character, but differs in having a distinct wing, more depressed form, and a recurvation of the strice along the post-umbonal slope.

Formation and localities. In the Chemung group, Philipsburg, Alleghany' county, N. Y., and Kelly's creek, Tioga county, Pa.

Lертореяма Нестов, н. sp.

PLATE XC, FIGS 49, 20

Shell of medium size, sub-rhomboidal; body narrowly elongate-ovate, oblique at an angle of about 30° with the cardinal line; length a little more than once and a half the height; ante-byssal margin oblique, curving into a broad, shallow sinus; ventral margin broadly curved; posterior margin abruptly recurved.

Left valve moderately convex below, narrowly gibbous above. Right valve depressed below, gently convex above.

Hinge-line straight; length equal to about four-fifths of the length of the valve.

Beaks sub-anterior, directed forward, acute, slightly elevated above the hinge. Umbonal angle very acute.

Anterior end narrow, small, produced into an acute extension, defined by a shallow byssal depression. Wing large, joining the body at three-fourths or more of its length from the beak; margin very oblique below, deeply sinuate just-beneath the cardinal line, turning abruptly backward and terminating in a spiniform extension. The wing of the right valve is searcely defined, and the shell has a somewhat broadly spatulate aspect.

Test thin, marked by fine, close, concentric striæ, and, as usually seen, the surface shows nearly equally distant lamellose striæ on the body and wing, which are crowded on the anterior side and extension. In the right valve these characters are more subdued on the body than on the wing. In ordinary conditions, the specimens mostly exhibit only obscure indications of the striation of the shell.

Muscular impression in the right valve large, sub-circular, placed below the middle of the length of the posterior slope.

A left valve, of the usual size, has a length of 35 mm., height 20 mm., hinge-line 27 mm. A small specimen has a length of 20 mm., height 12 mm., and hinge-line 16 mm. Young shells of this species are more gibbous than the older examples.

This species resembles, in its general form, L. extenuatum, but the body is narrower at the beak, the wing less extended, and the greatest concavity of the margin is just below the cardinal line; while in that species it is near the middle; the anterior extremity is also less prolonged.

Formation and locality. In the upper shales of the Chemung group near Canton, Bradford county, Pa.

LEPTODESMA CLITUS, n. sp. plate xc. fig. 21.

Shell of medium size, narrowly sub-rhomboidal; body elongate-ovate, oblique to the hinge-line at an angle of about 30°: length less than twice the height; ante-byssal margin very oblique: ventral margin broadly rounded, somewhat abruptly recurved at the post-basal extremity.

Left valve depressed-convex below, convex above, moderately gibbous on the umbo. Right valve unknown.

Hinge-line straight, less than the greatest length of the shell.

Beak sub-anterior, directed forward, moderately prominent. Umbonal region gibbous, subtending an acute angle.

Anterior end narrow, prolonged into a rostrate extension, defined by a strong byssal depression. Wing narrow-triangular, joining the body near the posterior end, defined only by the abrupt recurving of the striæ; margin deeply and abruptly concave, the deepest concavity about the middle; the extremity is an acute extension of the cardinal line.

Test thin, marked by fine concentric striæ, which are fasciculate upon the body, leaving the cast marked by gentle undulations, which are lamellose and elevated on the anterior side and rostral extension, and elevated on the wing.

Interior unknown.

A left valve has a length of 37 mm., height 20 mm., hinge-line 32 mm.

This species differs from *L. extenuatum* in its broader body, shorter hinge-line, and narrower wing; the strice bend more abruptly forward along the post-cardinal slope, and the wing margin is more deeply concave.

Formation and localities. In shales of the Chemung group at Kelly's creek and Mansfield, Tioga county, Pa.

Leptodesma truncatum, n. sp.

PLATE XC, FIGS, 24, 25,

Shell above the medium size, sub-rhomboidal; body ovate-elongate, oblique to the hinge-line at an angle of about 35°; length two-thirds greater than the height; ante-byssal margin oblique and often abruptly truncate, curving into the sinus; broadly rounded along the ventral margin, and more rapidly curving on the post-basal margin.

Left valve gently convex below, becoming more convex above, and somewhat gibbons on the umbo. Right valve less convex, flat in the lower part.

Hinge-line straight, nearly as long as the length of the shell.

Beaks sub-anterior, directed forward: in the left valve somewhat prominent; in the right valve not elevated above the hinge-line. Umbonal angle acute.

Anterior end obtuse, truncate, abruptly angular at the cardinal margin, limited by a slightly oblique byssal depression. Wing large, triangular, joining the body at the posterior extremity: margin sloping gently forward for two-thirds of the width, then abruptly recurved and extended in an acute or spiniform process. In the right valve the wing is less defined, and the anterior end is more strongly truncate.

Test thin, marked by sharp, elevated, distant, concentric striæ, with intermediate finer lines of growth. The stronger striæ are regular upon the wing and posterior part of the shell, fasciculate on the anterior side, and stronger and lamellose on the anterior extremity.

Interior unknown.

A left valve has a length of 38 mm., height 22 mm., and hinge-line 37 mm.

This species may be known by its truncate anterior end. The form of the body is very similar to *L. extenuatum*, but it is somewhat more convex and a little wider; the wing margin is less concave and the extremity less extended. The right valves of these two species are conspicuously different.

Formation and locality. In the central portion of the Chemung group, Mansfield, Tioga county, Pa.

LEPTODESMA CORYDON, n. sp.

PLATE XC, FIG. 22.

Shell above the medium size, sub-rhomboidal; body narrowing very rapidly toward the beak, oblique to the hinge-line at an angle of about 30°; length less than twice the height; ante-byssal margin oblique, nearly straight, slightly impressed at the sinus, broadly curved at the base and rounded on the posterior extremity.

Left valve depressed-convex below and slightly gibbous on the umbo (as preserved in thinly laminated shale). Right valve unknown.

Hinge-line straight, about equal to the greatest length of the shell.

Beak sub-anterior, directed forward, little elevated above the cardinal line. Umbonal region moderately gibbous, subtending an acute angle.

Anterior end narrow, rostrate, acute, extended, defined by a distinct, shallow, byssal depression which produces a long, gentle curvature in the margin of the valve. Wing narrow, joining the body at nearly the posterior extremity; margin abruptly recurved below and somewhat deeply concave a little below the cardinal line; extremity forming a spiniform extension.

Test thin, marked by fine concentric striæ, which are fasciculate on the body at unequal distances, and sharply elevated and more distinct on the wing.

Interior unknown.

A left valve of medium size has a length of 42 mm., height 25 mm., hinge-line about 40 mm.

Compared with *L. Clitus*, the body of the shell is more elongate-ovate or sub-spatulate, narrowing more rapidly toward the post-extremity; the wing is wider and the sinusity less deep, its greatest depth being near the cardinal line.

Formation and locality. In the Chemiung group, Kelly's creek, Tioga county, Pa.

LEPTODESMA JASON, n. sp.

PLATE XCL FIGS, 4-6.

Shell above the medium size, sub-triangular; body elongate-ovate or sub-spatulate, attenuate toward the anterior end, oblique at an angle of about 40° with the hinge-line; length once and a half the height; margin of the anterior end gently curving into the undefined byssal sinus; thence nearly straight to within one-fourth the length of the valve from the posterior extremity, which is regularly and broadly rounded.

Left valve regularly convex below, narrow and gibbous above. Right valve depressed-convex below, more convex above, and moderately gibbous in the umbonal region.

Hinge-line straight, somewhat less than the greatest length of the body. Beaks sub-anterior, acute, directed forward, slightly elevated above the hinge-line. Umbonal region abruptly gibbous, subtending a very acute angle.

Anterior end short. Wing joining the body near the posterior extremity; margin regularly concave, the greatest concavity near the middle of the width, terminating in a short spiniform extension. In the right valve the wing is proportionally larger and less defined.

Test thick, marked upon the body and wing with sharp, elevated, lamelliform strice and intermediate finer strice; on the anterior the strice are fasciculate.

Interior unknown.

A large left valve has a length of 40 mm., height 26 mm., hinge-line 32 mm. A right valve has a length of 36 mm., height 20 mm., and hinge-line 34 mm.

This species resembles L. Hector in general form, but is broader at the posterior end, more abruptly gibbous along the axis above the middle, the wing joins the body nearer the posterior extremity, and the margin of the wing has the deepest concavity in the centre of its width. The right valve is more convex than the right valve of L. Hector, and the concentric elevated striæ are

much stronger. In all these characters it also differs more extremely from L. extenuatum.

Formation and locality. In compact sandstone of the Upper Cheming group, alternating with some red beds, on Seely creek, Tioga county, Pa.

Leptobesma Pelops, n. sp.

PLATE XC. FIGS 28, 29,

Shell larger than the medium size, sub-rhomboidal: body ovate, oblique at an angle of about 40° with the hinge-line; height two-thirds the greatest length; ante-byssal and ventral margins very oblique and continuing in nearly a straight line for two-thirds the length, with a slight concavity for the byssal sinus; posterior margin very broadly curving.

Left valve depressed-convex below, gradually becoming more convex above the middle, and somewhat gibbous on the umbo. Right valve unknown.

Hinge-line straight, nearly equal to the greatest length of the shell.

Beak sub-anterior, inclined forward, obtuse, scarcely elevated above the hinge-line. Umbonal angle acute.

Anterior end triangular, prolonged, acute. Wing joining the body of the shell at the posterior extremity; margin symmetrically concave; extremity produced and acutely angular.

Test marked by distant, sub-equal, lamellose elevated striæ, with finer intermediate striæ. The stronger striæ are regular on the wing and posterior slope of the body, and become irregular and fasciculate on the anterior side and lower half.

Interior unknown.

The hinge shows a narrow striated ligamental area, and, apparently, a slender lateral tooth.

A large left valve has a length of 44 mm., height 28 mm., and hinge-line 42 mm.

This form is more oblique, and the wing is longer and narrower than in L. Orodes.

Formation and locality. In the Upper Chemiung group, Mansfield, Tioga county, Pa.

Leptodesma Orcus, n. sp.

PLATE XC, FIG. 23.

Shell of medium size, sub-rhomboidal; body ovate, straight on the posterior slope, oblique to the hinge-line at an angle of about 40°; length about one-third greater than the height; ante-byssal margin oblique, slightly impressed at the sinus, nearly straight along the base and regularly rounded posteriorly.

Left valve symmetrically and gently convex below, slightly gibbous above. Right valve unknown.

Hinge-line straight; length equal to three-fourths the length of the shell. Beak anterior, acute, little elevated above the hinge-line. Umbonal region narrowly gibbons, subtending a very acute angle.

Anterior end short, limited by an oblique byssal depression; extremity acute. Wing of medium size, joining the body about three-fourths its length from the beak; margin abruptly curving forward from the base to near the hinge-line, where it is sharply recurved into a short, angular extension of the eardinal line.

Test thin, marked by fine concentric striæ, which are somewhat fasciculate on the body and anterior part of the shell, and a little more sharply elevated on the wing.

Interior unknown.

The specimen illustrated has a length of 30 mm., height 22 mm., and hinge-line 24 mm.

The form and proportions of body are quite similar to *L. Lysander*, but it is wider on the posterior, narrower on the anterior end, and more oblique to the hinge; the striæ less sharply elevated, curving more forward along the posterior slope, and more abruptly recurved under the cardinal line.

Formation and locality. In the Chemiung group at Kelly's creek, Tioga county, Pa.

LEPTODESMA LYSANDER.

PLATE XXII, FIG. 22, AND PLATE XC, FIG. 34

Leptodesma Lysander, Hall. Pal. N. Y., vol. v., pt. 1. Plates and Explanations: Pl. 22, fig. 22. Jan., 1883.

Shell of medium size, sub-rhomboidal; body ovate, abruptly narrowing toward the front, oblique to the hinge-line at an angle of about 45°; length one-third greater than the height; ante-byssal margin oblique above, curving into the marked sinus, regularly rounded along the base and posterior extremity.

Left valve depressed-convex below, more convex above, and moderately gibbous on the umbo. Right valve unknown.

Hinge-line straight, about equal to the greatest length of the valve.

Beak sub-anterior, moderately prominent. Umbonal region but slightly gibbous, subtending an acute angle.

Anterior end broad, obliquely truncate; extremity slightly extended and acute. Wing narrow-triangular, joining the body at the posterior extremity; margin coneave, greatest concavity just above the middle, thence turning outward it is produced into a spiniform extension of the cardinal line.

Test marked by fine concentric striæ, with sharp lamellæ at nearly regular intervals over the body and wing, becoming crowded and fasciculate on the anterior of the shell.

Interior unknown.

 Λ specimen has a length of 35 mm., height 24 mm., and hinge-line 33 mm.

This species differs from L. Corydon in its shorter and broader form; the body is less oblique and more abruptly narrowed toward the anterior; the strike are less abruptly recurved along the posterior slope.

Formation and localities. In shales of the Chemning group at Kelly's creek and Mansfield, Tioga county, Pa.

LEPTODESMA NEREUS, n. sp.

PLATE XC, FIGS. 31-33.

Shell of medium size, sub-rhomboidal; body broadly ovate, narrowing rapidly to the anterior end, and oblique to the hinge-line at an angle of 45°; length less than one-third greater than the height; ante-byssal margin gently curved, extending into a wide sinus, broadly rounded along the base, curving regularly on the post-basal side and abruptly recurved in the upper part.

Left valve gently convex below, more convex above, and moderately gibbous on the umbo. Right valve smaller, more depressed below, nearly equally convex toward the umbo.

Hinge-line straight, less than the length of the valve.

Beaks sub-anterior, acute, directed forward, rising slightly above the hinge-line. Umbonal region gibbous in the left valve, narrower but equally gibbous in the right valve. Umbonal angle acute.

Anterior end small, abruptly curving into the byssal depression; extremity acute, not prolonged. Wing broad, extending along the body about four-fifths of its length from the beak; margin very oblique in the lower part and moderately concave above the centre, then turning abruptly backward just below the cardinal line, and produced into a short spiniform extension. In the right valve the wing is less defined and less concave on the margin.

Test thin, marked by concentric striæ, which are fasciculate on the body and anterior part, and more elevated, distant and sharp upon the wing.

Muscular impression large, sub-circular, situated on the posterior slope below the middle of the length. The pallial line extends from the lower part of the muscular impression nearly parallel to the anterior and basal margin. The hinge of the left valve has a strong groove extending its entire length; the right valve has an oblique posterior fold.

One specimen has a length of 35 mm., height 26 mm., hinge-line 31 mm. A similar example has a length of 34 mm., height 24 mm., and hinge-line 28 mm. A right valve has a greatest length of 31 mm., height 20 mm., and hinge-line 25 mm.

This species resembles L. Orcus, but the wing is wider, less deeply and abruptly sinuous, and the strice turn more abruptly forward at the junction of the body and wing. The body is narrower and more oblique than in L. Lysander, and the anterior end less prolonged.

Formation and locality. In the shales of the Upper Chemung group near Canton. Bradford county, Pa.

Leptodesma alatum, n. sp.

PLATE XC FIGS 26, 27.

Shell of medium size, sub-rhomboidal; body ovate, rapidly narrowing toward the beak, oblique, making an angle of about 50° with the hinge-line; length one-third greater than the height; ante-byssal margin oblique and curving into the distinct sinus; ventral margin gently curved, joining the broad, rounded, posterior extremity.

Left valve gently convex below, becoming more convex and slightly gibbous above the middle. Right valve depressed in the lower portion, in the middle and above about equally convex with the left.

Hinge-line straight, a little less than the length of the valve, and greater than the height.

Beaks sub-anterior, directed forward, acute, but little elevated above the hinge-line in the left valve. Umbonal region narrow, and abruptly gibbous. In the right valve the beak is depressed, and the umbonal region a little less gibbous than in the other valve.

Anterior end small, acute at the extremity, rounded below to the distinct byssal sinus. Wing large, wide-triangular, joining the body at the posterior extremity; margin moderately concave, the greatest concavity being above, the middle, from which point it turns abruptly outward and the extremity is produced into a spiniform extension. In the right valve the wing is less distinctly limited from the body than in the left.

Test thin, marked by sharp, elevated, concentric striæ, with finer intermediate lines of growth. The stronger striæ are somewhat regular upon the body and wing, while on the anterior side they are crowded and fasciculate.

Muscular impression large, sub-circular, situated below the middle of the posterior slope. The pallial line extends from the lower part of the muscular impression, parallel to the basal and anterior margins, into the cavity of the beak. Ligamental area wide.

A left valve of this species has a length of 35 mm., height 26 mm., and hinge-line 33 mm. A somewhat larger right valve has a length of 38 mm., height 28 mm., and hinge-line 33 mm.

Formation and locality. In the shales of the Chemung group at Canton, Bradford county, Pa.

LEPTODESMA ORUS, n. sp.

PLATE XC, FIG. 30,

Shell above the medium size, sub-rhomboidal; body broadly ovate, abruptly contracted towards the anterior end, oblique at an angle of about 50° with the hinge-line; ante-byssal margin oblique, curving into the marked sinus, thence gently curving to the posterior extremity, which is broadly rounded.

Left valve depressed-convex below, moderately convex above. Right valve unknown.

Hinge-line straight; length about five-sixths the greatest length of the valve.

Beak sub-anterior, directed forward, slightly rising above the cardinal line. Umbonal region moderately gibbous, subtending an acute angle.

Anterior end triangular, abruptly acute at the extremity, defined by a marked byssal depression. Wing large, triangular, without distinct limitation, joining the body near the posterior extremity; margin oblique below, concave above the middle, turning abruptly outward and terminating in a sharply angular extension of the cardinal line.

Test thin, marked by sharp, elevated, concentric striæ with finer intermediate ones. The stronger striæ are regular on the wing and posterior side; irregular and fasciculate on the anterior.

Interior unknown.

Two left valves have respectively these dimensions: length 48, and 42 mm.. height 32, and 30 mm., hinge-line 40, and 35 mm.

This species resembles L. Pelops, but the body is broader and less oblique, the anterior portion not so attenuate, the wing somewhat wider, the greatest sinussity in the margin of the wing being nearer to the cardinal line, and the extremity of the wing more acuminate.

Formation and locality. In shales of the Chemung group, Mansfield, Tioga county, N. Y.

LEPTODESMA ALIFORME.

PLATE XXII, FIG. 28; AND PLATE XCI, FIG. 2.

Leptodesma aliforme, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 22, fig. 28. Jan., 1883,

Shell large (right valve), elongate, triangular; body narrow, spatulate, oblique at an angle of about 30° with the cardinal line; length twice the height; margin of shell oblique anteriorly, continued along the base in nearly a straight line for two-thirds its length, thence curving to the posterior extremity, which is abruptly rounded.

Right valve nearly flat below, depressed-convex in the middle, slightly gibbous in the umbonal region. Left valve unknown.

Hinge-line straight; length equal to the greatest length of the shell.

Beak sub-anterior, depressed, directed forward.

Anterior end narrow-triangular; extremity attenuate, very acute. Wing narrow, elongate, triangular, extending to the posterior extremity of the valve, not defined; margin concave, the greatest concavity below the middle; extremity slightly produced, angular.

Test not preserved. The specimen is a cast of the interior, showing some faint indications of concentric striæ.

Muscular impression large, situated at about the middle of the length of the posterior slope. Pallial line continued parallel to the anterior side, with slight interruptions, nearly to the beak. The hinge is furnished with a slender, oblique lateral tooth. The specimen described is 60 mm. in length, with a height of 29 mm., and hinge-line 61 mm.

This species bears considerable resemblance to *L. extenuatum* in the characters of the right valve; but it is proportionally narrower, the posterior extremity more abruptly recurved and the hinge-line less extended behind. A single right valve is the only specimen at present known. It differs sufficiently from the other forms here described to be easily recognized.

Formation and locality. In a white sandstone of the middle portion of the Chemung group near Angelica, Alleghany county, N. Y.

LEPTODESMA RUDE.

PLATE XXV, FIG. 12; AND PLATE XCI, FIG. 3.

Leptodesma rude, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 25, fig. 12. Jan., 1883.

Shell large, sub-rhomboidal: body broadly ovate below, rapidly attenuating above, oblique to the hinge-line at an angle of about 50°; length less than one-third greater than the height; ante-byssal margin curving into the broad sinus; ventral and posterior margins broadly rounded.

Left valve convex below, becoming narrow and gibbous above the middle. Right valve less convex.

Hinge-line straight, less than the length of the valve.

Beak sub-anterior, directed forward, acute, little elevated above the cardinal line. Umbonal region narrow and gibbous, subtending an acute angle.

Anterior end large, limited by a vertical byssal depression; extremity acute. Wing of moderate size, joining the body at the posterior extremity; margin concave; termination acute.

Test thick, marked by concentric striæ, which have been fasciculate, leaving strong undulations upon the east of the interior. These surface characters are subdued in the right valve.

Interior unknown.

A left valve has a length of 51 mm., height 37 mm., hinge-line about 42 mm.

Specimens of this species usually present a very rough and irregular aspect from the character of the shell, with its strongly lamellose structure and the coarse matrix in which it is usually found. The specimen figured is a east of the interior, and is distinguished by the broad posterior end and abrupt narrowing toward the front, the obtusely sub-angular umbo, and the large anterior end. In a crushed specimen retaining both valves, the right valve is almost equally convex with the left; the surface is less lamellose and presents only gentle undulations.

Formation and locality. In a coarse sandstone of the upper part of the Cheming group, on the road from Olean, N. Y., to Smethport, Pa.

Leptodesma Biton, n. sp.

PLATE XCL FIG. 1.

Shell large, sub-rhomboidal; body elongate-ovate, making an angle of about 45° with the hinge-line; height nearly two-thirds of the length; ante-byssal margin oblique, slightly curving into a long, shallow sinus, which impresses the margin for more than half the length of the valve; basal and posterior margins broadly rounded.

Left valve regularly and gently convex in the lower part, becoming more convex and gibbous above the middle. Right valve unknown.

Hinge-line straight, greater than the height of the valve.

Beak sub-anterior, directed forward, but little elevated above the hingeline. Umbonal region abraptly gibbous, subtending an acute angle.

Anterior end produced, narrow, acute at the extremity, limited by an oblique, shallow byssal depression. Wing large, joining the body at the posterior end, not distinctly separated; margin slightly oblique below, gently concave above the middle, and curving slightly outward just below the cardinal line.

Test thin: cast marked by fine concentric strice of growth, which, at

intervals, have been elevated into fascicles, and on the external shell, were probably sharp lamellose striæ.

Interior unknown.

The specimen described has a length of 50 mm., height 31 mm., and hinge-line 35 mm.

This species resembles L. Orodes, and may be distinguished by the more extended and acute anterior extremity, and the larger wing which is distinctly concave on the margin and recurved just below the cardinal line. It differs from L. Maclurii in its more produced anterior extremity, and broader wing which is less abruptly recurved at the extremity.

Formation and locality. In a coarse sandstone of the Upper Chemung group, south of Smethport, McKean county, Pa.

Leptodesma Lesleyi, n. sp.

PLATE XCI. FIG. 7.

Shell large, sub-rhomboidal; body narrow, elongate-ovate, making an angle of 30° with the cardinal line; length more than one-third greater than the height; ante-byssal margin oblique, nearly straight above, curving into the broad sinus; ventral margin broadly curved; posterior extremity abruptly rounded.

Left valve convex below, narrowly gibbous in the middle and on the umbo. Right valve less convex, depressed below.

Hinge-line straight, nearly equal to the greatest length of the shell.

Beaks sub-anterior, directed forward, acute and arching over the hinge in the left valve, depressed in the right valve. Umbonal region of the left valve narrowly gibbous, and subtending a very acute angle.

Anterior end large, limited by a broad, distinct, oblique byssal depression; extremity tlattened and acuminate. Wing large, triangular, joining the body near the post-basal extremity, limited by the abrupt forward bending of the strice; margin deeply concave; extremity produced and acute. The

wing of the right valve is searcely defined from the body and less deeply concave on the margin.

Test marked by fine, irregular, concentric striæ which are strongly fasciculate and lamellose on the ventral side and anterior end, and are shown on the wing as sharp, elevated, regular striæ. Some specimens preserve fine regular striæ on the body of the valve, but they are usually somewhat irregular and lamellose. In an exfoliated and macerated condition they show fine radiating lines which probably belong to the intimate structure of the shell.

Ligamental area (as preserved in an imperfect right valve) 1.5 mm. wide, and marked by very fine, minutely undulating longitudinal striæ. The hinge also shows an obscure oblique lateral tooth.

A left valve, of medium size, has a greatest length of 56 mm., height 31 mm., and hinge-line about 51 mm.

This species somewhat resembles L. aviforme, but is distinguished by its more oblique form, and wider anterior end. Specimens are quite abundant in an argillo-calcareous sandstone of the Upper Chemung group, associated with Spirifera Verneuili.

Formation and locality. In the Upper Chemung group, Auburn township, Susquehanna county, Pa.

LEPTODESMA AVIFORME, n. sp.

PLATE XCI, FIG. 8.

Shell large, sub-rhomboidal; body elongate-ovate, broad behind, and rapidly narrowing toward the beak, oblique at an angle of a little less than 45° to the hinge-line; height more than one-half the length; ante-byssal margin very oblique, continued in a straight line into the shallow sinus, thence curving to the posterior extremity, which is broadly rounded.

Left valve gently convex below, very convex above, and moderately gibbous on the umbo. Right valve unknown.

Hinge-line straight; length a little more than the greatest length of the valve.

Beak sub-anterior, directed forward, acute, not rising much above the hinge. Umbonal angle acute.

Anterior end narrow, elongate, very acute, limited by a shallow byssal depression. Wing large, joining the body near the base; margin broadly and symmetrically concave; extremity produced into a spiniform extension reaching beyond the posterior extent of the shell.

Test marked by fine concentric striæ which are regular on the posterior part of the body and the wing, and very crowded and fasciculate on the anterior.

Interior unknown.

A large left valve has a length of 60 mm., height 37 mm., hinge-line 62 mm. A slightly larger, imperfect specimen has been found, the body of which, near the posterior extremity, has a greatest width of from 25 to 28 mm., and measures from 12 to 14 mm. in the narrow part between the beak and the byssal sinus.

This species differs from *L. Pelops* in the longer and more erect body, more attenuate anterior extremity, more extended wing and deeper sinus in the margin.

Formation and localities. In the middle beds of the Chemung group at Charleston, and near Mansfield, Tioga county, Pa.

Section d, patulata.

LEPTODESMA FLACCIDUM, n. sp.

PLATE XCI, FIG. 9.

Shell of medium size, rhomboid-ovate, spatulate below; body oblique at an angle of about 45° to the hinge-line; length about one-third greater than the height; ante-byssal margin subtruncate, oblique, a little concave below, curving into the broad ventral margin; posterior margin abruptly rounded and recurved.

Left valve moderately convex in the middle, gibbous on the umbo, depressed-convex in the lower part. Right valve unknown.

Hinge-line straight; length about equal to the height of the shell.

Beak obtuse, directed forward, moderately prominent, situated anterior to the middle of the cardinal line. Umbonal region gibbous, subtending an acute angle.

Anterior end comparatively large, produced into a nasute extension. Wing small, narrow-triangular, joining the body of the shell more than one-third the height above the base; margin gently concave; extremity acute.

Test thin, marked by fine regular strike of growth, which are fasciculate on the umbo and lamellose at nearly equal intervals on the lower part of the shell.

Interior unknown. The hinge is marked by a single slender groove.

A left valve has a length of 40 mm., height 27 mm., hinge-line about 27 mm.

This species resembles *L. complanatum*, but differs in its greater proportional length and the body is more depressed and extended below. It is characterized by the spatulate posterior extension, which is more extreme than in any other species here described.

Formation and locality. In the Chemung group, Lawrenceville, Tioga county,

Leptodesma patulum, n. sp.

PLATE XCI, FIGS, 10, 41

Shell above the medium size, sub-rhomboidal; body oblique, elongate, sub-ovate; length slightly more than one-third greater than the height; ante-byssal margin oblique, gradually curving to the ventral margin which is nearly straight; posterior margin broadly curved.

Valves moderately convex below, searcely gibbons above, similar in form; the right valve being a little smaller and less convex than the left.

Hinge-line straight, somewhat longer than the height of the shell.

Beaks at about the anterior third of the hinge-line, directed forward,

somewhat prominent. Umbonal region moderately gibbous, not strongly defined. Umbonal angle acute.

Anterior end large, produced into a nasute extension. Wing large, joining the shell at the posterior extremity; margin scarcely concave, abruptly produced along the hinge-line.

Test marked by fine lines of growth which are irregularly fasciculate, sometimes appearing as equidistant, sharply elevated lamellæ; crowded on the anterior; more regular over the wing and abruptly recurving just beneath the hinge.

The hinge is marked by one or two narrow, parallel, longitudinal grooves.

A specimen of medium size has a length of 40 mm., height 26 mm., and hinge-line 28 mm. A similar right valve has a length of 36 mm., height 24 mm., and hinge-line 27 mm.

This species differs from L. flaccidum in its much larger wing, which is more extended along the body of the shell. It is less convex and the umbo less gibbous than in any of the preceding species.

Formation and locality. In the upper part of the Chemiung group at Mansfield, Tioga county, Pa.

LEPTODESMA COMPLANATUM.

PLATE XXII, FIG 2.

Leptodesma complanatum, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 22, fig. 2. Jan., 1883.

Shell of medium size, obliquely semi-elliptical; body sub-ovate, moderately oblique; length one-third greater than the height; ante-byssal margin subtruncate, gradually curving into the broad ventral margin; posterior margin abruptly rounded.

Left valve depressed-convex, a little gibbous on the umbo. Right valve unknown.

Hinge-line straight; length less than the height of the shell.

Beak acute, incurved, directed forward, moderately prominent. Umbonal

region indistinctly defined anteriorly; the posterior side limited by the postnmbonal depression.

Anterior end short; extremity angular. Wing undefined, joining the body one-third of the length from the posterior extremity; margin gently concave; extremity scarcely produced.

Test marked by fine, sharply elevated, concentric striæ, which are more crowded anteriorly, and very regular on the wing.

Interior unknown.

The specimen described, which is a separate left valve, has a length of 28 mm., height 20 mm., and hinge-line 18 mm.

Formation and locality. In the shales of the Chemung group at Philipsburg, N. Y.

Section e, arcoidea.

LEPTODESMA MACLURII.

PLATE XXV, FIGS. 8, 13; AND PLATE XCI, FIGS. 13, 14.

Leptodesma Maclurii, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 25, figs. 8, 13. Jan., 1883.

Shell large, rhomboidal; body elongate, sub-elliptical, oblique, making an angle of about 45° with the hinge-line; length more than one-third greater than the height; ante-byssal margin oblique, gently curving into a long, shallow, undefined sinus; ventral margin nearly straight, curving abruptly into the posterior margin, which is rounded and abruptly recurved.

Left valve moderately convex in the lower part, becoming gibbous and sub-angular along the line of the axis to the beak. Right valve distinctly arcuate, less convex, narrowly gibbous in the umbonal region.

Hinge-line straight; length about equal to the height of the valve.

Beaks sub-anterior, directed forward, but little elevated above the hingeline in the left valve, depressed in the right. Umbonal angle acute.

Anterior end narrow-triangular, limited by an oblique depression which extends nearly one-third of the length of the valve to the byssal sinus.

Wing large, undefined; margin very oblique in the lower part, slightly concave above, the greatest concavity being a little below the hinge-margin; extremity produced into an angular extension. The right valve shows less distinction between the body of the valve and the wing.

Test thin, marked by distant lamellose lines of growth with intermediate finer striæ. These lines are more regular upon the wing and very much crowded and fasciculate upon the anterior side of the body.

Interior unknown.

Hinge, posterior to the beak, furnished with a slender lateral tooth

A left valve of this species has a length of 55 mm., height 35 mm., hingeline 37 mm., and the body, at the posterior end, having a width of 25 mm. A right valve has a length of 45 mm., height 30 mm., and hinge-line about 28 mm.

The specimens of this species observed are casts of the interior in coarse sandstone, or impressions of the exterior in the same rock. The species is distinguished by its straight ventral side and the nearly parallel direction of the sides of the body in the left valve.

Formation and localities. In a coarse sandstone of the Upper Chemung group, on the road from Olean, N. Y., to Smethport, Pa., and at Bradford, Pa.

Leptodesma arciforme, n. sp.

PLATE XCI, FIG. 12.

Shell large, narrow, sub-rhomboidal; body sub-cylindrical, oblique at an angle of about 30° to the hinge-line; length nearly one-half greater than the height; anterior margin oblique, merging into the broad, low curvature of the ventral margin; posterior margin abruptly rounded and curving into the undefined wing.

Valves very convex, strongly gibbous, obtusely sub-angular along the middle; the greatest convexity distant from the beak one-third the height of the valve. The right valve is less gibbous, but otherwise similar to the left.

Hinge-line straight; length about equal to the height of the shell.

Beaks prominent, directed forward and arching over the hinge, situated at about the anterior third of the cardinal line. Umbonal region angularly gibbous above, abruptly defined along the posterior slope. Umbonal angle acute.

Anterior end short, angular. Wing an undefined, narrow-triangular expansion; margin straight or a little concave; extremity very slightly produced.

Test moderately thick, marked by fine concentric striæ, which are fusciculate on the body of the shell, and crowded and lamellose over the anterior side.

Interior unknown.

A large left valve has a length of 60 mm., height 36 mm., and hingeline 37 mm.

This species is distinguished from L. Lichas by its larger and stronger form, being very gibbous along the entire length of the shell, and with a proportionally smaller wing.

Formation and locality. In the upper part of the Chemung group at Mansfield, Tioga county, Pa.

Leptodesma Phaon, n. sp.

PLATE XCI, FIG. 18.

SHELL above the medium size, narrow-rhomboidal; body sub-cylindrical, very oblique, making an angle with the hinge-line of less than 30°; length nearly twice the height; ante-byssal margin short, oblique, curving into the broad, almost straight ventral side; posterior margin abruptly but regularly rounded and continuous with the base of the wing.

Left valve very convex, gibbous above. Right valve unknown.

Hinge-line straight, somewhat longer than the height of the shell.

Beak at the anterior third of the hinge-line, obtuse, moderately elevated, directed forward. Umbonal region gibbous, not well-defined anteriorly, abruptly depressed on the posterior. Umbonal angle acute.

Anterior end short, acute at the extremity, defined by a slight bend in the strice indicating the byssal sinus. Wing small, narrow-triangular, joining the body near the posterior end; margin straight, very oblique: extremity angular.

Test marked by strong concentric striæ, which at equal intervals are raised into sharp lamellæ, and are more crowded in front.

Interior unknown.

A left valve has a length of 47 mm., height 25 mm., and hinge-line 27 mm.

This species is remarkable for its extreme obliquity of body. In its general features it somewhat resembles *L. arciforme*, but differs in the less angular gibbosity of the body, larger wing, more extended anterior end, and in the surface markings.

Formation and locality. In the upper part of the Chemung group at Mansfield, Tioga county, Pa.

LEPTODESMA PROPINQUUM, 11. Sp.

PLATE XCI, FIGS, 16, 17,

Shell of medium size, rhomboidal; body narrow, sub-cylindrical, very oblique, making an angle of about 30° with the hinge-line; length more than twice the height; anterior margin oblique; ventral margin nearly straight on the anterior half, and broadly curving over the lower half; posterior margin abruptly curved.

Valves gibbous, nearly equal in size and convexity.

Hinge-line straight, longer than the height of the valve.

Beaks at about the anterior third of the hinge-line, directed forward, very prominent, arching over the cardinal line. Umbonal region gibbous, limited posteriorly by the vertical descent of that side, scarcely defined on the anterior. The umbo and post-cardinal slope are obtusely sub-angular for about two-thirds of the length of the body. Umbonal angle acute.

Anterior end not defined (the byssal depression being obsolete); extremity acute. Wing small, narrow-triangular, joining the body near the posterior

extremity, undefined; margin straight or slightly concave, very oblique; extremity slightly produced, angular.

Test marked by regular, even, concentric striæ, which, when well preserved, are elevated and lamellose, and are crowded and fasciculate on the anterior end of the shell.

Interior unknown.

A nearly entire left valve has a greatest length of 45 mm., height 20 mm., and hinge-line 26 mm. A similar right valve has a length of 37 mm., height 18 mm., and hinge-line 22 mm.

This species is very similar to L. Lichas, but differs in the greater convexity of body, undefined by sal depression, and narrower wing.

Formation and locality. In the middle portion of the Chemung group at Mansfield, Tioga county, Pa.

LEPTODESMA LICHAS.

PLATE XXI, FIGS. 35-39; AND PLATE XCI, FIGS. 19, 20.

Leptodesma Lichas, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 21, figs. 35-39. Jan., 1883.

Shell of medium size, sub-rhomboidal; body sub-cylindrical, very oblique; length nearly twice the height; ante-byssal margin subtruncate, extending below to the broad, gently curving base; posterior margin abruptly recurved.

Valves very convex above, gently convex toward the posterior extremity, making the body somewhat cylindrical. Right valve probably a little shorter than the left, as inferred from the separated valves.

Hinge-line straight, less than the length of the shell.

Beaks acute, situated at the anterior third of the hinge-line, directed forward, prominent, arching over the cardinal line. Umbo abruptly gibbous, subtending an acute angle.

Anterior end large, acute and nasute at the extremity. The byssal sinus makes only a slight depression in the margin. Wing narrow-triangular, joining the body near the posterior extremity, not distinctly limited; margin

straight and oblique below, recurving just beneath the hinge-line, and forming a short mucronate extension.

Test thin, marked by fine concentric striæ which are irregularly crowded into fascicles, producing an undulated aspect to the surface. The striæ are sub-lamellose on the anterior side, and sometimes fasciculate on the wing. The fascicles on the body are often marked on their summits by sharp, regular lamellæ. The structure as seen in exfoliated specimens is radiated; but this does not appear to be an exterior character.

The hinge is marked by a single narrow groove; beyond this the characters of the interior are unknown.

A large left valve has a length of 45 mm., height 25 mm., hinge-line 27 mm. A smaller specimen has a length of 28 mm., height 16 mm., hinge-line 17 mm. A right valve has a length of 26 mm., height 15 mm., and hinge-line 15 mm.

Formation and localities. In the Chemung group at Philipsburg, Alleghany county, N. Y., and in Sullivan township, Tioga county, Pa.

LEPTODESMA QUADRATUM, n. sp.

PLATE XCI, FIG. 15.

Shell of medium size, rhomboidal or sub-quadrate; body ovate, making an angle of nearly 40° with the cardinal line; length one-third greater than the height; ante-byssal margin nearly vertical in front, rounding below into the shallow sinus, and extending nearly the whole height of the valve; ventral margin nearly straight; post-basal margin abruptly rounded and joining the wing without limitation.

Left valve convex, gibbous on the umbo, and obscurely angular along the posterior slope. Right valve equally convex.

Hinge-line straight, equal to three-fourths the length of the valve, and equal to the height.

Beaks situated at the anterior third of the hinge, prominent and arching over the cardinal line. Umbonal region gibbous, subtending an acute angle.

Anterior end convex, limited by a shallow, oblique, byssal depression which is nearly as long as the height of the valve; length one-half the height; extremity slightly produced. Wing triangular, scarcely defined, joining the body at the posterior extremity; margin oblique, straight or slightly convex; extremity obtuse-angular. An imperfect right valve presents about the same characters of wing.

Test marked by fine strike of growth which are strongly fasciculate on the anterior end.

Interior unknown.

A left valve has a greatest length of 31 mm., height 20 mm., and hingeline 21 mm.

This species is distinguished by its short, broad, sub-quadrate form. It has very much the aspect of Modiomorphia, but clearly belongs with *L. Phaon* and *L. Lichas*, which are among the extreme variations of the species of Leptodesma.

Formation and locality. In the Upper Chemung group, Lindley township, Steuben county, N. Y.

Section f, mytiloidea.

LEPTODESMA ACUTIROSTRUM, n. sp.

PLATE XCI, FIG. 21.

Shell of medium size, rhomboid-ovate; body narrowly ovate and rapidly attenuate toward the beak, oblique, making an angle of a little less than 45° with the hinge-line; length nearly one-third greater than the height; ante-byssal margin oblique, sloping into the shallow sinus; broadly rounded below, the curvature continued into the posterior extremity.

Left valve depressed-convex in the lower part, moderately convex in the middle, and slightly gibbons above. Right valve unknown.

Hinge-line straight, less than the height of the valve.

Beak anterior, acute, directed forward, scarcely rising above the hinge-

line. Umbonal region narrow and moderately gibbous, subtending a very acute angle.

The byssal depression reaches the margin just below the beak, leaving a very small, acute, anterior extremity. Wing large, undefined, joining the body at the posterior end; margin oblique, essentially straight, not recurved at the cardinal extremity.

Test thin, leaving upon the east the marks of the strike of growth which are more or less fasciculate upon the body, and crowded and lamellose in front.

Hinge furnished with a distinct posterior tooth. Interior unknown.

The specimen described has a length of 32 mm., height 24 mm., and hinge-line 22 mm.

This species somewhat resembles *L. Orodes*, especially as shown in Pl. xxv, fig. 10, but the beak is more nearly anterior, the anterior end much smaller and more acute, the byssal sinus not extending so low on the body of the valve, and the body of the shell more distinctly attenuate toward the beak. It is especially distinguished by its narrow slender beak and small anterior end.

Formation and locality. In a sandstone of the Upper Chemiung group at Warren, Pa.

LEPTODESMA MYTILIFORME.

PLATE XXV, FIGS. 7, 11; AND PLATE XCI, FIGS. 22-25.

Leptodesma mytiliforme, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 25, figs. 7, 11. Jan., 1883.

Shell of medium size, elongate-ovate; body narrowly elliptical, becoming attenuate in front, oblique, making an angle of nearly 45° with the hingeline; length more than one-third greater than the height; ante-byssal margin oblique, gently curving into a searcely perceptible sinus, giving a straight or slightly coneave margin extending for two-thirds the length of the valve; posterior margin abruptly rounded.

Left valve regularly convex in the lower half, becoming contracted, gibbous and sub-angular above the middle. The right valve is smaller, the hinge-line proportionally longer, the base of the valve and the wing much more depressed, and the umbonal region narrow and more angular.

Hinge-line straight, about equal to the height of the valve.

Beaks sub-anterior, directed forward, acute, scarcely raised above the hinge-line. Umbonal region narrow and gibbons, subtending a very acute angle.

Anterior end short, abruptly attenuate, acute, limited by a shallow byssal depression which extends for half the length of the valve. Wing large, not strongly limited, extending nearly to the posterior extremity of the body; margin very oblique, not concave, nor recurved below the cardinal line; extremity obtuse-angular.

Test thin, marked by concentric strike which have left their impression upon the cast of the interior, showing them to have been regular upon the body and wing, and crowded into fascicles upon the anterior side.

Ligamental area narrow and finely striated. Interior unknown.

The largest specimen of the left valve observed has a length of 48 mm., height 25 mm., and hinge-line 22 mm. A smaller example has a length of 33 mm., height 22 mm., and hinge-line 20 mm. A large right valve has a length of 40 mm., height 25 mm., and hinge-line 27 mm.

This species differs from L. Mentor in its proportionally longer, narrower and sub-angular body, the smaller, less defined wing, the less distinct byssal sinus, and the smaller anterior end. The wing is often imperfect, giving the shell much the aspect of Mytilus or Modola. The axis of the shell in the left valve is apparently slightly curved, giving it a characteristic expression.

Formation and locality. In a coarse sandstone of the Upper Chemung group, on the road from Olean, N. Y., to Smethport, Pa.

PTERONITES. McCoy.

Pteronites profundus.

PLATE XXII, FIGS, 25, 26, 27,

Pteronites profundus, Hall. Pal. N. V., vol. v, pt. 1. Plates and Explanations: Pl. 22, figs. 25-27.

Jan., 1883.

SHELL large, longitudinally semi-ovate: body semi-elliptical, arcuate, oblique to the hinge-line at an angle of about 30°; length about twice the height; anterior margin very oblique, slightly concave beneath the beak and gradually curving into the broadly rounded basal margin; posterior margin obliquely truncate, slightly curving below.

Left valve convex in the lower part, gibbous from the middle upwards. Right valve unknown.

Hinge-line straight; length more than the greatest length of the shell.

Beak sub-anterior, obtuse, rising but little above the hinge-line, and apparently not incurved. Umbonal region very gibbous, subtending an acute angle.

Anterior end produced into an acute extension which is limited by a very shallow byssal depression. Wing not defined, extending from the beak the entire length of the shell, and produced beyond the posterior extremity of the body; margin very slightly concave, extending at nearly right angles to the axis of the body.

Test of moderate thickness, marked by concentric striæ. The casts show distant, irregular, concentric undulations.

Hinge with a single continuous groove. The pallial line extends parallel to the ventral margin, from a point anterior to the beak to below the middle of the length of the body.

A large left valve has a length of 78 mm., with a height of 38 mm., and hinge-line 90 mm. A smaller example has a length of 37 mm., height 23 mm., and hinge-line 40 mm.

All the specimens of this species are easts of the interior, with the single exception of an individual which preserves the test very imperfectly. The concentric undulations of the east are often a conspicuous feature, and the umbonal slope is occasionally obtusely subangular. The wing follows the general contour and convexity of the valve.

Formation and localities. In the Upper Chemung group, associated with Spirifera Verneuili near Olean, Alleghany county; in the vicinity of East Randolph, and other places in Cattaraugus county, N. Y.

Pteronites rostratus.

PLATE XXII, FIG. 24.

Pteronites rostratus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations; Pl. 22, fig. 24. Jan., 1883.

Shell of medium size, broadly semi-ovate; body oblique at an angle of about 45° to the hinge-line; length nearly twice the height; ante-byssal margin oblique, gently curving into the broadly rounded basal margin; posterior margin somewhat obliquely truncate.

Left valve depressed-convex below, convex in the middle, and somewhat gibbous above. Right valve unknown.

Hinge-line straight; length greater than the greatest length of the shell. Beak sub-anterior, sub-acute, prominent. Umbonal region moderately gibbous, subtending an acute angle.

Anterior end nasute. Wing not defined, in direct continuation of the convexity of the body, extending to the posterior extremity; margin very slightly coneave, oblique to the cardinal line, slightly produced at the extremity.

Test ornamented by fine, elevated, concentric striæ, which are continued over the body and wing without interruption, becoming crowded and somewhat fasciculate on the anterior side and on the nasute extension in front.

The umbonal region shows a few concentric undulations, which are not continued to the middle of the length of the valve.

Interior unknown.

The specimen described has a length of 29 mm., height 16 mm., and hingeline 31 mm.

This species is much smaller than *P. profundus*, less elongate and less gibbous in its proportions. The beak is apparently more elevated and angular, but the angularity of the umbonal region is not continued along the body as in the preceding form.

Formation and locality. In the shales of the Chemung group at Rockville, Alleghany county, N. Y.

PTERONITES INOPTATUS, n. sp. PLATE LXXXVII, FIG. 5.

SHELL of medium size, broadly semi-ovate; body ovate, oblique, making an angle of about 25° with the cardinal line; ventral and basal margins broadly rounded; post-basal extremity abruptly recurved.

Left valve regularly convex, slightly gibbous above. Right valve unknown. Hinge-line straight, less than the greatest length of the shell.

Beak sub-anterior, directed forward, prominent and incurved over the cardinal line. Umbonal angle acute.

Anterior end short, nasute; extremity acute. Wing very narrow-triangular, scarcely defined, joining the body at the posterior extremity; margin oblique, in direct continuation with the posterior extremity and curving backward just beneath the cardinal line; extremity acute.

Test marked by concentric strike of growth which are strongly fasciculate on the anterior end and ventral margin.

Interior unknown.

The left valve described has a length of 38 mm., height 21 mm., and hinge-line 33 mm.

This species is distinguished from the other forms of this genus by its narrow wing and shorter hinge-line. It has the characteristic aspect of Pteronites although approaching, in several particulars, to some species of Leptodesma.

Formation and locality. In the Chemung group, Mansfield, Tioga county, Pa.

PALÆOPINNA, HALL.

Palæopinna flabella.

PLATE XXV, FIG. 18; AND PLATE LXXXVII, FIG. 4.

Palwopinna flabella, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 25, fig. 18.

Jan., 1883.

Shell large, broadly semi-ovate, gaping at the anterior extremity; axis oblique to the hinge at an angle of about 30°; length nearly twice the height; byssal margin abruptly truncate; ventral margin very broadly curving; posterior margin oblique, sub-truncate.

Left valve depressed-convex in the posterior and ventral portions, becoming more convex above and moderately gibbous in the umbonal region. Right valve unknown.

Hinge-line straight, equalling the greatest length of the shell.

Beak anterior, terminal, prominent, directed forward, scarcely rising above the cardinal line. Umbonal region subtending an acute angle.

Anterior end abruptly truncate; margin excavate. Wing continuous with the body of the shell without limitation or interruption; margin directed backward, nearly straight, continuous with the post-basal margin of the body; extremity abruptly rounded.

Test thin, marked by regular concentric strike of growth which are cancellated by fine sub-equal radii; in the cast the concentric and radiating strike are of nearly equal strength. On the anterior end the radii are obscure or obsolete as preserved in the cast.

Ligamental area narrow, marked by a single longitudinal groove and a slight oblique furrow extending backward from the beak a little more than one-third the length of the hinge.

The left valve described has a length along the hinge-line of 80 mm., height 40 mm.; measured along the axis of the body the length is about 70 mm., and the anterior truncation is 25 mm. long.

The specimen described is a cast of the interior, preserving the surface markings in a subdued condition. The anterior margin appears to have been slightly incurved and the truncation resembles that in some forms of Solex.

Formation and locality. In the Oriskany sandstone, Schoharie, N. Y.

PALÆOPINNA RECURVA.

PLATE XXV, FIG. 19.

Palæopinna recurva, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 25, fig. 19. Jan., 1883.

Shell large, elongate semi-elliptical; axis making an angle with the hinge-line of from 20°-25°; length greater than twice the height: basal margin very broadly curving; posterior margin rapidly rounding and recurving toward the beak.

Left valve depressed-convex below, convex above and becoming gibbons toward the beak. Right valve unknown.

Hinge-line straight, not extending as far as the posterior extremity.

Anterior end unknown. Wing not defined: margin continuous with the post-basal margin and abruptly incurving at the extremity.

Test thin, marked by fine sub-equal strike of growth, which become lamellose on the pallial margin; and by radii of unequal strength, which are are sometimes strongly erenulated by the concentric strike. Anterior to the middle of the shell the radii are obscure.

Interior unknown.

The specimen described is imperfect on the anterior end but preserves a length of 120 mm., and a height 62 mm.

This species differs from the preceding in its larger size, broadly rounded posterior extremity, and the hinge not extending as far as the posterior margin; the body is also more oblique and less convex.

Formation and locality. In limestone of the Upper Helderberg group, Stafford, Genesee county, N. Y.

ECTENODESMA, HALL

Ectenodesma birostratum.

PLATE XXIII, FIGS, 27-30; AND PLATE LXXXIV, FIG. 20

Ectenodesma birostratum, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 23, figs. 27-30.

Jan., 4883.

Shell large; body ovate, oblique; height greater than the length; margin regularly curving from the base of the anterior wing to the post-basal margin, where it is somewhat abruptly recurved.

Left valve regularly convex below, gibbons in the umbonal region, somewhat arcuate, the point of greatest convexity being about the middle of its length. Right valve concave below, depressed-convex in the middle, convex on the umbo.

Hinge-line straight, much longer than the length of the shell, and, in extreme specimens, more than once and a half greater than the length of the shell.

Beaks acute, anterior to the middle of the shell, inclined forward, and arching over the hinge-line. Umbonal region gibbous, limited on the anterior side by a shallow undefined sulcus, and on the posterior side by the abrupt depression of the body, subtending an acute angle.

Anterior wing large, triangular; margin concave; extremity produced to an acuminate extension. Byssal sinus shallow and undefined. Posterior wing large, triangular, joining the body below the middle of its height; margin concave; extremity produced into an acute termination.

Test of left valve marked with regular and even radii which are rounded above, flattened and sometimes bifurcate below; similar but more acute radii continue over the posterior wing. In the right valve the rays are more numerous, finer and sharp, and are continued upon the posterior wing with a little less force than on the body of the shell; and very much subdued upon the anterior wing; entire surface marked by fine, even, concentric striæ of growth.

The specimens show an oblique lateral tooth, with obscure indications of anterior teeth or folds. Ligamental area narrow, marked with fine parallel striæ.

A left valve has a length of 45 mm., height 50 mm., hinge-line, when entire, about 75 mm. A small right valve has a length 34 mm., height 27 mm., hinge-line about 45 mm.

This species is distinguished by the great and nearly equal extent of the hinge-line on both sides of the beak; by the peculiar form of the body of the shell; and by its surface characters, which are unlike any yet observed.

Formation and localities. In the Chemung group at Franklin, Delaware county; and a right valve referred to this species is from a point four miles above Chenango Forks, Chenango county, N. Y.

LIMOPTERA, HALL.

LIMOPTERA PAUPERATA.

PLATE XXVI, FIG. 5.

Limoptera pauperata, Hall. Prelim. Notice Lam. Shells, etc., pt. 2, p. 16. Dec, 1869.

Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 26, fig. 5. Jan., 1883.

Shell large; body ovate, sub-erect; wing greatly expanded; height much greater than the length; basal margin broadly rounded; posterior side gently eurving from the post-basal extremity to the beak.

Left valve somewhat regularly convex from the umbo to the base. Right valve unknown.

Hinge-line straight, longer than the greatest length of the valve.

Beak of the left valve prominent, inclined forward, rising above the hinge-line, situated anterior to the middle of the body of the shell. Umbonal region moderately gibbons, abrupt on the anterior, and more gently sloping on the posterior side.

Auricle and byssal sinus unknown. Wing large, triangular, not distinctly limited from the body, and extending nearly to the post-basal extreinity of the shell; margin slightly concave; extremity abrupt (rectangular?).

Test marked by strong rounded radii, with alternate smaller ones; or finer bifurcating rays between, which are somewhat curved as they approach the beak. The entire surface of the shell is marked by fine concentric striæ, which become crowded and lamellose, obscuring and partially obliterating the rays; the striæ on the lower part of the body are conspicuous, and also on the wing and especially toward the hinge-margin. In the cast the rays show a somewhat nodose character which is probably due to the unequal weathering of the concentric lamellæ.

Interior characters and ligamental area unknown.

The specimen described has an approximate height of 75 mm., and a length of 65 mm. (The figure is incorrect in its proportions.)

This species differs from L. macroptera, and from L. cancellata, in its lesser gibbosity and its much stronger radii. A single, ill-preserved, specimen from the Hamilton group, possesses characters similar to this species, but the identity of the two cannot be positively determined without more material.

Formation and locality. In the higher beds of the Upper Helderberg limestone at Stafford, Genesee county, N. Y.

LIMOPTERA CANCELLATA.

PLATE XXVI, FIGS. I-4; AND PLATE XCII, FIGS. I-3.

Limoplera cancellata, Hall. Prelim. Notice Lam. Shells, etc., pt. 2, p. 16. Dec., 1869.
" " " " Miller, Cat. Amer. Pal. Foss., p. 193. 1877.

" Pal. N. Y., vol. v, pt. 1, Plates and Explanations: Pl. 26, figs. 1-4, Jan., 1883.

Limoplera cancellata, var. occidens, H. and W. Twenty-Fourth An. Rep., N. Y. State Museum Nat. Hist., p. 199, pl. 11, figs. 12-15. 1872.

Shell large; body sub-creet, broadly ovate; axis nearly vertical to the hingeline; wing expanded; height and length nearly equal; ventral margin very broadly rounded; anterior margin expanded below and contracted above; post-basal side expanded, recurving somewhat abruptly and extending in a sub-arcuate line to the beak.

Valves very unequal. Left valve moderately convex below, gradually

becoming gibbous and arcuate above. Right valve concave below, flat in the middle and depressed-convex in the umbonal region.

Hinge-line straight, less than the length of the valve.

Beak of left valve prominent, anterior to the middle of the valve, acute, inclined forward and arching over the hinge-line. Umbonal region prominent, gibbous, abruptly limited on either side. In the right valve the beak does not rise above the cardinal line. Umbonal region defined on the anterior side by a distinct oblique fold or ridge, and on the posterior side by a well-marked depression limiting the wing, subtending an acute angle.

Ear small, limited by a shallow sinus below. Wing large, triangular, extending more than half the height of the shell toward the base; margin gently concave and slightly recurving toward the hinge-line: extremity angular.

Test of moderate thickness, marked by somewhat distant, rounded, abruptly elevated radii, with wider intermediate flat spaces which are sometimes marked by one or more smaller rays. In the partial cast, these rays are crossed, and the intermediate spaces cancellated, by fine concentric striæ. Towards the ventral and baso-lateral margins the shell is lamellose and the radii become obsolete. The concentric striæ are crowded upon the wing, and the radii are less conspicuous than on the body of the shell.

Ligamental area in left valve large; smaller in the right valve. The pallial line in the left valve forms a distinct nodose ridge, which extends from the rostral cavity in a slightly arcuate line to below the middle of the valve. In the right valve, the pallial line in the cast extends along the ridge, limiting the body of the shell from the anterior alation. In the cast of the left valve, the umbonal cavity is marked by numerous nodes indicating pits in the shell for muscular attachment. The posterior muscular impression is large, occupying the post-umbonal slope at a point about half-way from the beak to the base of the shell.

A cast of the interior has a length of about 78 mm., height 77 mm., and hinge-line less than the length of the shell.

This species is distinguished by its erect form, the broad flat interspaces between the radii, and the regular sharp concentric striæ.

Formation and locality. The specimen is from the higher beds of limestone at the Falls of the Ohio, which are of the age of the Hamilton group.

LIMOPTERA MACROPTERA.

PLATE XXIV, FIG. II., PLATE XXVI, FIGS. 6-9; PLATE XXVII, FIGS. 1-10; PLATE XXVIII, FIGS. 4,5; PLATE XXIX, FIGS. 1-1; AND PLATE XXII, FIGS. 4-9.

```
Lima macroptera, Conrad. Annual Report N. Y. Geolog, Surv., p. 117.—1838.

Limoptera macroptera (Conrad), Hall. Prelim. Notice Lam. Shells, etc., pt. 2, p. 17.—Dec., 1869.

" " S. A. Miller, Cat. Amer. Pal. Foss.—1877.

" " Hall. Pal. N. Y., vol. v, pt. 1.—Plates and Explanations; Pl. 24, fig. 14;
pl. 26, figs. 6-9; pl. 27, figs. 1-10; pl. 28, figs. 4, 5; and pl. 29, figs. 1-4.—Jan., 1883.
```

Shell large: including the cardinal expansions, the form is subquadrate; body broadly ovate, erect or moderately oblique; wing more or less expanded; height one-fourth to one-third greater than the length; basal margin broadly rounded, with the anterior and posterior sides sub-parallel.

Valves very unequal. Left valve ranging from moderately convex to very gibbous, often somewhat regularly arcuate from beak to base. Right valve smaller than the opposite, in young specimens nearly flat below, depressed-convex in the middle, and more convex in the umbonal region; in specimens of medium size there is often a greater convexity in the upper part, and in very old specimens the surface is depressed-convex and nearly flat in the lower part.

Hinge-line straight, sometimes equalling but usually less than the length of the shell.

Beak of the left valve prominent, acute, inclined forward, rising above and arching over the cardinal line, situated anterior to the middle of the body of the shell. Umbonal region prominent, convex in young shells and gibbons in older ones, limited anteriorly by a distinct sulcus, and posteriorly by the abrupt umbonal slope. Beak of right valve acute, scarcely rising above the hinge-line, defined anteriorly by the byssal sulcus, and posteriorly by the abrupt depression and distinct limitation of the wing. Umbonal angle acute.

Ear small, well-defined in young specimens, and searcely increasing in size in proportion to the growth of the shells, limited by a distinct byssal depression: extremity rounded. Wing large, triangular; margin more or less concave in young shells, and often nearly straight in older shells; extremity produced or rectangular, often extending beyond the posterior margin of the valve.

Test thick, especially in the umbonal region; marked by distinct sub-equidistant, rounded radii, with slightly concave interspaces, in which are often finer, or obscurely developed rays: the right valve is usually more closely and less strongly marked by them than the left. The radii are crossed and crenulated by elevated, lamellose, concentric striæ, which are more distant and conspicuous on the right valve. In the young shells, the radii are conspicuous on the wing; they are a little more distant than on the body of the shell, and often obsolete along the line of the junction of the wing with the body, especially in the right valve. In both valves, the radii become obscure or obsolete below the centre, and the surface is marked by strong, irregular, concentric, lamellose undulations. The radii often become more or less obsolete upon the wing, while remaining conspicuous on the body of the shell.

Ligamental area extending the entire length of the hinge-line, much wider in the left valve: marked by coarse parallel, undulating, longitudinal grooves or striæ. There is a conspicuous oblique posterior lateral tooth, and two strong cardinal folds beneath or just anterior to the beak. Anterior muscular impression situated in the rostral cavity; the pallial line continues thence in a curve somewhat parallel to the margins of the shell, turning inward below the middle of the height and joining the large muscular impression.

The right valve of a young individual (plate xxiv, fig. 14) has a length of 30 mm., height 35 mm., and hinge-line 32 mm. The margin of the left valve, which remains in the matrix, shows it to have had a length of 42 mm., and a height of 53 mm. Another specimen, with the two valves attached, has the left valve 75 mm. and the right valve 55 mm. in height, while the

length of the two valves respectively is 63 and 43 mm. In another specimen (plate xxvii, figs. 6 and 7), where the two valves are in juxtaposition, there appears to be little difference in the relative dimensions, but this appearance is in a great measure due to the fact that the margins of the left valve have been broken away to the line of junction of the two valves. The proportional dimensions of the left valves are subject to much variation, as is shown in plate xxvii, figs. 2 and 3.

The measurement of two large specimens gives respectively, length 78 and 74 mm., height 90 mm. each, and hinge-line 58 and 65 mm. A large specimen with the margin imperfect has a length of 88 mm., and height 112 mm. A separated right valve has a length of 97 mm., height 103 mm., and hinge-line 84 mm.

The young shells of this form, especially the right valves, might readily be mistaken for Aviculopecten or Pterinopecten; but a critical examination will show the radii to be peculiar and characteristic of the genus.

The form and proportions of the fossil are subject to great variations in their natural conditions, but the variation and distortions of form, consequent upon the degree and direction of pressure from the inclosing matrix, produces much greater extremes. Some of the distorted forms are illustrated on plates xxviii and xxix. In the older specimens, the obliteration or obsolescence of the radii below the middle of the valve, gives a great variety of aspect to the fossil. These variations are illustrated on plates xxvi, xxvii and xxviii.

In all the younger specimens, the wing is produced, and the margin sinuate, while the surface is distinctly marked by the radii. These features are gradually lost as the shell advances in age, until the margin of the wing becomes nearly or quite direct, the extremity of the wing obtuse, and the surface marked only by the concentric strike of growth. In old specimens the ear is often obscure, and scarcely retains the proportionate size of that appendage in the younger shells.

Formation and localities. In the Hamilton group, at Cazenovia and other localities in Madison county, and in Otsego and Onondaga counties, N. Y.

Limoptera obsoleta.

PLATE XXIX, FIGS. 5, 6; PLATE XXVI, FIG. 10?; AND PLATE XCII, FIG. 10.

Limoptera of soleta, Hall. Prelim. Notice of Lam. Shells, etc., pt. 2. Dec., 1869.

Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 29, figs. 5, 6. Jan., 1883.

Shell large; body ovate, erect or slightly oblique; height greater than the length; basal margin regularly rounded; anterior side broadly convex and contracting to the byssal sinus; posterior side abruptly recurved from the base, and extending in a nearly direct or slightly concave line to the extremity of the wing.

Valves very unequal. The right valve much depressed or nearly flat; the left valve depressed-convex below, regularly convex in the middle, and gibbous in the umbonal region.

Hinge-line straight, nearly rectangular to the axis of the body of the shell, less than the length of the valve.

Beak of left valve prominent, acute, inclined forward, situated anterior to the middle of the body, rising much above the beak of the right valve, and arching over the cardinal line. Umbonal region prominent, and sometimes gibbous, limited anteriorly by a distinct broad depression, and posteriorly by the abrupt umbonal slope; subtending an acute angle.

Ear small, limited by the byssal sinus. Wing moderately large, triangular, extending below the middle of the length of the body; extremity abruptly rounded.

Test thick, marked by irregular concentric strike of growth, which are crowded and strongly lamellose on the lower half of the body and on the anterior and posterior sides. On the wing, just below the cardinal line, the strike turn gently outward. In some specimens there remain obscure indications of radii.

Ligamental area wide, extending the entire length of the hinge-line; marked by coarse undulating strice and wider intermediate grooves. Other characters of the hinge and interior not observed.

One of the specimens figured has a height of 88 mm., and another of 100

mm.; the approximate length is 70 mm. and 88 mm., respectively. Another specimen has a length of 77 mm., and a height of 90 mm. A larger specimen has a length of 90 mm., and a height of 100 mm.

The specimens of this species occur in the softer shales of the Hamilton group, and it is possible that long maceration has had some influence in obliterating the radii; but *L. macroptera*, with its more convex form, and marked by its characteristic radii, occurs in the same localities. Although not entirely satisfied in regard to its specific distinction, it may be convenient to separate this at least as a varietal form.

Formation and localities. In the Hamilton group, at Hamilton, Madison county, at Delphi, Onondaga county; and on the shore of Cayuga lake, N. Y.

LIMOPTERA CURVATA.

PLATE XXVIII, FIGS. I-3.

Limoptera curvata, Hall. Prelim. Notice, Lam. Shells, etc., part 2, p. 18. Dec., 1869.

"Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 28, figs. 1-3. Jan., 1883.

Shell large, sub-rhomboid-ovate in outline; body broadly ovate, arenate, expanded on the antero-basal margin.

Valves very unequal. Left valve very gibbous in the middle and umbonal region. Right valve depressed-convex below, becoming somewhat gibbons on the umbo. Left valve, with the beak, very prominent and incurved; beak of right valve rising but little above the hinge-line.

Test thick, marked by strong rounded radii with intermediate finer lines which become obsolete on the lower part of the valve. The radii are crossed by fine, closely arranged strike of growth, which at intervals are crowded and lamellose, especially toward the margin of the valve.

The internal cast shows the anterior muscular impression situated at the extremity of the rostral eavity, from which the pallial line, marked by a row of strong pustules, extends nearly parallel to the anterior margin for more than one-third the length of the valve; thence broadly curving, it extends below the middle of the valve, and recurves into a large sub-circular

muscular impression on the post-umbonal slope. The interpallial area is finely pustulose.

This variety was originally separated from L. macroptera by reason of its proportionally broader, shorter, and more gibbous form; the arcuation of the body of the left valve, and its expansion on the antero-basal margin. In a single example of the left valve, the radii are much stronger than usual in typical specimens of the other form, and the interstitial radii more strongly developed. These characters, and others upon which the species was originally founded, when compared with a large number of individuals of the genus, are represented with many modifications, and the specific distinction is here continued with much reservation.

On comparing the typical specimen of Mr. Conrad's *L. macroptera*, we find it proportionally shorter and wider than many specimens since referred to the same species; measuring 63 mm. in length and about 78 mm. in height, the left valve very gibbous and the body sub-arcuate; the proportions being very nearly the same as in *L. curvata*, represented in fig. 2, of plate xxviii.

Formation and localities. This species occurs in the Hamilton group at Cazenovia and other places in Madison county, N. Y.

BYSSOPTERIA, HALL.

Byssopteria radiata.

PLATE XXXII, FIGS. 21, 22; AND PLATE LXXX, FIG. 11.

Mytilarca radiata, Hall. MS. 1877.

" " S. A. Miller, Cat. Amer. Pal. Fossils, 1877.

Byssopteria radiata, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 32, figs. 21, 22; pl. 80, fig. 11. Jan., 1883.

Shell large, wide-triangular, alate posteriorly; body undefined; length about five-sevenths of the height; anterior margin vertically truncate the entire height of the shell; basal and posterior margins broadly rounded.

Valves sub-equal, depressed-convex on the basal and post-basal sides, sub-angularly gibbous on the umbo and along the anterior side.

Hinge-line straight, less than the length of the shell. Beaks anterior, acute, elevated, and directed forward. Anterior end sub-nasute.

Test marked by strong, sub-equal, rounded radii which are wider than the interspaces, often bifurcating below the middle of their length, and on the outer portion of the undefined wing they are fasciculate and finer. Entire surface marked by strike of growth which become elevated into fascicles toward the margins.

Interior unknown.

A right valve has a length of 55 mm, and height 72 mm. A left valve measures 54 mm, in length, and 79 mm, in height.

This species is unlike any Pectinoid or Aviculoid form described in this volume, and has somewhat the aspect of several species of Ambonyoma from the lower rocks, although probably very distinct in its generic relations.

Formation and locality. In the Upper Chemung group at Mansfield, Tioga county, Pa.

MYTILARCA, HALL.

SUB-GENUS PLETHOMYTILUS, HALL.

Mytilarca (Plethomytilus) arenacea.

PLATE XXX, FIG. 1; AND PLATE LXXXVII FIG. 10.

Mytilarea arenacea, Hall. Prelim. Notice Lam. Shells, etc., pt. 2, p. 20. Dec., 1869.

"S. A. Miller in Cat. Amer. Pal. Foss. 1877.

Plethomytilus " Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 30, fig. 1. Jan., 1883.

Shell of medium size; body ovate, acute at the apex, slightly oblique; height equal to about three-fourths of the length. Byssal area concave; margin straight below to a point three-fourths of the length from the apex; abruptly curving to the posterior and basal margins; post-basal and dorsal margins gently curving to the extremity of the hinge-line.

Valves moderately convex below, becoming gibbons in the umbonal region, and upon the anterior umbonal slope.

Hinge-line straight and short. Beaks anterior, prominent, rising above the cardinal line, moderately incurved. Umbonal angle acute. Posterior alation narrow and short, merging into the general contour of the margin above the middle of the length of the shell.

Test thick, marked by fine concentric strike of growth, which at somewhat regular intervals are crowded, and raised into imbricating lamellae, as shown in casts of the interior.

A valve of the ordinary size measures about 60 mm. in length, and 45 mm. in its greatest height.

The fossils of this species are known only as casts of the interior, in an arenaceous matrix, and are usually more or less imperfect, the narrow posterior alation being rarely preserved in connection with the body of the shell.

Formation and localities. In the Schoharie grit at Schoharie, and in the Helderberg mountains, Albany county, N. Y.

Mytilarca (Plethomytilus) ponderosa.

PLATE XXX, FIGS, 2-7

Mytilarca ponderosa, Hall. Prelim. Notice Lam. Shells, etc., pt. 2, p. 21. Dec., 1869.

Plethomytilus ponderosus, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 30, figs. 2-7, Jan., 1883.

Shell very large; body acutely ovate, erect; height three-fifths the length;* ventral margin nearly straight or slightly concave for about one-half the length of the shell; posterior and basal margins abruptly rounded; dorsal margin gently curved to the extremity of the hinge-line.

Valves equal, regularly convex posteriorly, gibbons above and in the umbonal region.

Hinge-line straight and short. Beaks anterior, prominent, rising much above the cardinal line, moderately incurved. Ventral side concave with a slight inflation of the margin at the byssal opening. Dorsal side sub-alate.

Test thick, marked by concentric strike of growth which become lamellose toward the margin.

Ligamental area finely and evenly striated longitudinally, in old shells becoming very wide, indicating great thickness of the test.

Interior unknown.

A large specimen, which is a cast of the interior, has a length of 135 mm., height 80 mm., breadth 80 mm. A small example has a length of 36 mm. and height 23 mm.

This species differs from Mytilarca (P.) arenacea in its greater size and gibbosity; from M. (Plethomytilus) cordiformis, Hall=M. (P.) myilimera, Corrad, and M (P.) ovata, Hall, from the Lower Helderberg group, in its more elongate form and more attenuate apex.

Formation and localities. In the limestone of the Upper Helderberg group, Helderberg mountains, Albany county, N. Y.; Clarence Hollow, Erie county, N. Y.; and in limestone of the same age at Columbus, Ohio, and Walpole, Ontario.

^{*}In the mytiloid forms the length is measured from the beak to the posterior extremity and the height is at right angles to this. The breadth represents the convexity of the valves.

Mytilarca (Plethomytilus) oviformis.

PLATE XXXI, FIGS. 1-8: AND PLATE LXXXVII, FIG. 8.

Inoceramus oviformis, Conrad. Jour. Acad. Nat. Sei., Phila., vol. viii, p. 246, pl. 13, fig. 7.—1842.

Mytilarca oviformis (Conrad), Hall. Prelim. Notice Lam. Shells, etc., pt. 2, p. 21.—1869.

Plethomytilus oviformis (Conrad), Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 31, figs. 1-8.—Jan., 1883.

Shell large; body ovate, erect, wide posteriorly and acute above; length about one-fifth greater than the height; ventral margin for nearly half the length of the shell nearly direct, thence gently curving into the posterior extremity which is broadly rounded; dorsal margin very gently curved.

Valves equal, regularly convex in the posterior part, becoming gibbous in the umbonal region.

Hinge-line straight, less than the height of the shell. Beaks prominent, anterior acute, and incurved, rising above the cardinal line.

Ventral side truncate with a small fold for the passage of the byssus. Dorsal side sub-alate.

Test thick, marked by fine, close strike of growth which at intervals are fasciculate and raised into lamellose elevations and very much crowded and elevated on the ventral side of the shell.

Ligamental area wide, finely striated longitudinally and occasionally preserving one or two oblique folds which may have been lateral teeth. Other characters of the interior unknown.

A large specimen has a length of 74 mm, and height 55 mm. A small example measures 25 mm, in length and 17 mm, in height.

This form differs from M. (P) ponderosa in its greater proportional height, smaller size, and lesser gibbosity.

Formation and localities. In the shales of the Hamilton group at numerous localities in Schoharie, Otsego, Onondaga. Ontario, Livingston and Erie counties, N. Y.

Mytilarca (Pletnomytilus) Knappi, n. sp.

PLATE LXXXVII, FIG. 13

SHELL of medium size; body ovate, obtuse, broad below; height nearly equal to the length; ventral margin rounded with a slight sinusity at the byssal opening; dorsal margin broadly rounded.

Right valve moderately convex below, somewhat more convex in the umbonal region. Left valve unknown.

Hinge-line less than the height of the shell. Beak obtuse.

Test thin below, thicker on the upper part and cardinal line. Surface marked by fine, regular, elevated strike of growth.

Ligamental area narrow, coarsely striated longitudinally.

Interior unknown.

The right valve described has a length of 48 mm. and height 44 mm.

This species differs from M. (P.) oviformis in its proportionally greater height, less attenuate beak, lesser convexity and the coarsely striated ligamental area. The relations of this species are somewhat obscure, owing to the obscure limitation of the beak and the effects of maceration and compression. It is however clearly distinct from any of the forms here described.

Formation and locality. In the shales of the Hamilton group on the shores of Skaneateles lake, N. Y.

MYTILARCA PYRAMIDATA.

PLATE LXXX, FIGS 1-3.

Mytilarca pyramidata, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 80, figs. 1-3. Jan., 1883.

Shell of medium size; body sub-angularly ovate, pyramidal; length one-third greater than the height; ventral margin truncate and concave, curving abruptly into the basal margin; dorsal margin very gently curving to the beaks.

Valves equal, convex, gibbous above, and sub-angular along the anterior umbonal slope. The ventral side is rectangularly incurved.

Hinge-line short. Beaks acute, extremely elevated, directed slightly forward and curving over the cardinal line.

The test has not been preserved. The casts are nearly smooth, but showing lamellose strike on the pallial margin.

Interior unknown.

A specimen of this species has a length of 36 mm., height 23 mm., breadth 22 mm.

This form is shorter, more gibbous, more attenuate towards the beak, and less rounded on the posterior side than M. Chemungensis.

Formation and locality. In the Schoharie grit, Schoharie county, N. Y.

MYTILARCA UMBONATA.

PLATE XXXII, FIGS. 1-7.

Mytilarca umbonala, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 32, figs. 1-7. Jan., 1883.

SHELL small to medium size; body ovate, acute above; length more than one-third greater than the height; ventral margin truncate, inflated at the byssal opening; basal margin abruptly rounded.

Valves equal, strongly convex in the lower part and narrowly gibbons in the umbonal region. Ventral umbonal slope obtusely angular, concave between this and the ventral margin. Dorsal side not alate.

Hinge-line short. Beaks acute, elevated, nearly vertical, arching over the cardinal line.

Test thin, marked by fine concentric lines of growth which become crowded and lamellose toward the pallial margin.

Interior unknown.

A specimen has a length of 33 mm., height 18 mm., breadth 19 mm.

This species differs from M. Chemungensis in its shorter and more gibbous form; the beaks more elevated and erect.

Formation and localities. In the Middle Chemung group, Ithaca, N. Y., and near Mansfield, Pa.

MYTILARCA CHEMUNGENSIS.

PLATE XXXII, FIGS 8-11, 13, 14.

Inoceramus Chemungensis, Conrad. Jour. Acad. Nat. Sci., Phila., vol. 8, p. 246, pl. 13, fig. 9, 1842.

Mytilus Chemungensis (Conrad), Phillips and Salter. Memoirs Geolog. Surv. of Great Britain, vol. 2, pt. 1, p. 365, pl. 20, figs. 10, 11, 1848.

Mytilarca Chemungensis (CONRAD), HALL. Prelim. Notice Lam. Shells, etc., p. 23. 1869.

Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 32, figs.8-14 (pl. 33, fig. 8, in error). Jan., 1883.

Shell of medium size, much elongated from beak to posterior extremity; body narrow, elongate-ovate, sub-arcuate; length averaging twice the height but with considerable variation; ventral margin nearly straight, slightly concave for nearly three-fourths of the length; basal margin abruptly rounded; dorsal margin gently curving.

Valves equal, convex in the posterior part, gibbous above; the greatest convexity a little above the middle. The ventral umbonal slope is obtuse, sloping nearly vertically to the ventral margin.

Hinge-line short, oblique. Beaks elevated, acute, anterior, slightly incurved.

Test thin, marked by very fine concentric striæ, which toward the margins are often fasciculate and sub-imbricating.

Ligamental area finely striated longitudinally. Cardinal teeth small, diverging, situated immediately under the beak. Other characters of the interior unknown.

The proportions of length and height are subject to great variation. A short example has a length of 26 mm. and height 17 mm. A specimen of ordinary proportions has a length of 53 mm. and height 26 mm. An elongate form has a length of 56 mm. and height 22 mm.

This species differs from M. carinata in its comparatively longer form: the ventral umbonal slope less angular; and the body less arcuate.

Formation and localities. In the middle portion of the Chemung group, Rockville, Hobbieville and Phillipsburgh, Alleghany county, and East Randolph, Cattarangus county, N. Y.

MYTILARCA CARINATA.

PLATE XXXII, FIGS. 15-19; AND PLATE XXXIII, FIG. 8.

```
Mytilarca carinata, Hall. MSS. 1877.

" " S. A. Miller, in Cat. Amer. Pal. Foss., p. 197, 1877.

" Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 33, figs. 15-19.

Jan., 1883.
```

Shell of small or medium size; body obliquely sub-ovate: length nearly twice the height, except in young specimens; ventral margin nearly straight or slightly concave for more than three-quarters of the length of the shell, thence rounding abruptly into the basal margin, then more gently rounded into the gently curving dorsal margin.

Valves equal, depressed-convex in the posterior part, becoming moderately convex in the middle and scarcely gibbous above. The ventral umbonal slope is angular, and the shell between it and the margin is concave.

Hinge-line short, less than the height of the shell. Beaks anterior, prominent, acute, slightly curving forward.

Test thin, marked by very fine concentric striæ of growth, which are crowded on the anterior side and toward the base.

Ligamental area of moderate width, finely striated longitudinally. Cardinal teeth small, diverging, situated under the extremity of the beak. Lateral teeth two, small, oblique, situated just below the posterior extremity of the hinge-line. Other characters of the interior unknown.

A specimen has a length of 30 mm. and height 18 mm. A more elongate form has a length of 43 mm. and height 20 mm. A small individual has a length of 23 mm. and height 15 mm.

This form differs from *M. Chemungensis* in its proportionally shorter form, the young shells have a sub-triangular aspect, the ventral umbonal slope is always angular, and the body is more distinctly arcuate.

Formation and localities. In the middle portion of the Chemung group, Tioga and Chemung counties, N. Y.

MYTILARCA REGULARIS, n. sp.

PLATE XXXII, FIG. 12.

SHELL above the medium size: body narrowly ovate: length less than twice the height; byssal area scarcely depressed: ventral margin for two-thirds the length nearly straight, thence curving into the posterior margin which is regularly rounded; dorsal margin gently curving to the extremity of the cardinal line.

Left valve gently and regularly convex in the posterior half, convex above and searcely gibbous on the umbo. Right valve unknown.

Hinge-line straight, short, oblique. Beak nearly erect, acute and abruptly attenuate.

Test thin, marked by fine elevated concentric strike which are crowded on the ventral and dorsal sides of the valve.

Ligamental area narrow, longitudinally striated.

Interior unknown.

The specimen described has a length of 48 mm, and height 28 mm.

As compared with *M. Chemungensis* this species has a proportionally wider form; it is more nearly equilateral, the umbonal elevation is less abrupt and more nearly central. It is proportionally higher than *M. occidentalis* and less elevated along the umbonal slope.

Formation and locality. In a sandstone of the Cheming group, near Leon Centre, Cattaraugus county, N. Y.

MYTILARCA ATTENUATA.

PLATE XXXII, FIG. 20.

Mytilarca altenuata, Нац. Prelim. Notice Lam. Shells, etc., pt. 2, p. 23.—1869.

"Pal. N. Y., vol. v., pt. 1.—Plates and Explanations: Pl. 32, fig. 20.—Jan., 1883.

Shell above medium size; body extremely elongate, sub-cuneiform; length nearly three times the height; ventral margin nearly straight for almost the entire length, with a slight depression at the byssal opening; posterior

margin abruptly rounded, gently curving into the dorsal margin which is straight above the middle.

Right valve gently convex in the posterior part, becoming gibbous and angular in the umbonal region. Left valve unknown.

Beak erect, acute, pointed.

Test of moderate thickness, marked by fine concentric striæ of growth, which at intervals have been raised into lamellæ which have left strong varices upon the cast.

Interior unknown.

A right valve has a length of 65 mm. and height 24.5 mm.

This species differs from *M. Chemungensis* in its more elongate, straighter form, and in the angularity of the umbonal slope. From *M. carinata* it is distinguished by its elongate form, straight ventral side, and more prominent anterior umbonal slope.

Formation and locality. In the arenaceous beds associated with fossils of the middle Chemung group, from a loose mass collected at Elmira, N. Y.

MYTILARCA SIMPLEX.

PLATE XXXIII, FIGS. 19, 21,

Mytilops (Modiola) simplex. Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 33, figs. 19, 21 (20 in error) Jan., 1883.

SHELL of medium size; body elongate-ovate, with an acute apex; length nearly twice the height; byssal area depressed; margin below nearly straight for two-thirds the length; posterior margin abruptly rounded; dorsal margin gently curving to the hinge-line.

Valves equal, moderately convex in the posterior part, and gibbous on the umbo. The line of greatest convexity is on the ventral side of the axis.

Hinge-line short. Beaks sub-erect, acute, abruptly attenuate.

Test marked by fine, closely arranged, concentric striæ.

Ligamental area and interior unknown.

A specimen has a length of 41 mm, and height 25 mm.

This species is somewhat intermediate to *M. Chemungensis* and *M. regularis*, but is distinguished from the former by its shorter form, and from the latter by its greater convexity and more attenuate beak. This form and the succeeding, were referred to Mytilops, but a careful comparison shows them to be related to the species here arranged under Mytilarca.

Formation and locality. In the sandstones of the Cheming group, west of Smethport, Pa.

Mytilarca gibbosa, n. sp.

PLATE XXXIII, FIG. 20; AND PLATE LXXXVII, FIG. 7.

Shell of medium size; body ovate-archate, obliquely truncate along the hingeline; length less than twice the height: ventral margin nearly straight for more than three-fourths the length, abruptly curving into the posterior margin, thence gently rounded to the extremity of the hinge-line.

Left valve very convex; the greatest convexity above the middle. Umbonal region gibbous. Right valve unknown.

Hinge-line oblique, nearly equal to the height of the shell. Beak small, appressed, arching toward the ventral side.

Test marked by fine concentric striæ, which, at irregular intervals, are crowded into fascicles, leaving varices upon the surface of the cast.

Interior unknown.

The specimen described has a length of 45 mm., and height 26 mm.

This species is proportionally longer, beak more acute, and much more gibbous than M. lata.

Formation and locality. In the Upper Chemung group, Napoli, Cattaraugus county, N. Y.

Mytilarca lata.

PLATE XXXIII, FIG. 22.

Mytilops (Modiola) lata, Hall. Pal. N. Y., vol. v. pt. 1. Plates and Explanations: Pl. 33, fig. 22 Jan., 1883.

Shell large; body broadly sub-elliptical, abruptly narrowing toward the beak on the dorsal side; length one-third greater than the height; byssal area

slightly inflated, thence nearly straight for almost three-fourths the length of the shell; posterior margin broadly rounded; dorsal margin gently curved for two-thirds of the length and then truncated in nearly a direct line to the beak.

Right valve moderately convex in the posterior part, becoming broadly convex in the middle, and somewhat gibbous in the umbonal region. Left valve unknown.

Hinge-line oblique; extent unknown. Beak elevated, erect, acute.

Test marked by rather coarse, elevated lines of growth.

Interior unknown.

The specimen described has a length of 60 mm. and height 40 mm.

This species somewhat resembles *M. regularis* but the beak is more anterior, the body wider and more convex, and the truncation of the cardinal margin is much longer.

Formation and locality. In the Chemung group, Randolph, Cattaraugus county, N. Y.

MYTILARCA OCCIDENTALIS.

PLATE XXXIII, FIGS. 3-5; AND PLATE LXXXVII, FIG. 11.

Mytilus occidentalis, White and Whitfield. Proc. Boston Soc. Nat. Hist., vol. viii, p. 297. 1862.

Mytilarea occidentalis (W. and W.), Hall. Prelim. Notice Lam. Shells, etc., pt. 2, p. 24. 1869.

" " " Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 33, figs. 3–5. Jan., 1883.

SHELL above the medium size; body extremely elongate, narrow-ovate: length more than twice the height; ventral margin a little inflated at the byssal opening, then gently curving to the posterior margin which is abruptly rounded, and broadly curving along the dorsal side.

Valves equal, convex in the posterior part, becoming gibbous below the middle and anteriorly; the greatest convexity is anterior to the middle.

Hinge-line short. Beaks acute, nearly erect. The umbonal region is narrow and the convexity is continued along the median line to the posterior end of the shell.

Test thin, marked by numerous-fine concentric striæ, which at irregular intervals have been raised into imbricating lamellæ, leaving strong varices on the east.

Interior unknown.

A specimen has a length of 52 mm, and height 25 mm.

This species is distinguished from *M. Chemungensis* by its straighter form, erect beaks, and convexity along the medial line.

Formation and locality. In the Yellow sandstones, at Burlington, Iowa.

MYTHLARCA FIBRISTRIATA.

PLATE XXXIII, FIGS. 6, 7; AND PLATE LXXXVII, FIG. 6.

Mytitus fibristriatus, White and Whitfield. Proc. Boston Soc. Nat. Hist., vol. viii, p. 296. Feb., 1862.

"Whitfieldianus, Winchell. Proc. Acad. Nat. Sci., Phila., p. 413. Sept., 1862.

"p. 11. 1863.

Mytilarca fibristriata, (W. and W.), Hall. Prelim. Notice, Lam. Shells, etc., pt. 2, p. 24. 1869.

"fibristriata (W. and W.) (fimbristriata, in error), Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 33, figs. 6, 7. Jan., 1883.

Shell of medium size; body very elongate, narrow elliptical; length more than twice the height; byssal area convex and inflated; ventral margin nearly straight for two-thirds the length, thence curving into the abruptly rounded posterior extremity; dorsal margin very gently curved to the extremity of the hinge-line.

Valves equal, moderately convex in the posterior part, becoming gibbous in the middle and anterior.

Hinge-line short, oblique. Beaks narrow, sub-erect. Umbonal region narrowly gibbous.

Test thin, marked by fine, thread-like, undulating radii, which are more or less interrupted by the fine concentric striæ.

Interior unknown.

A specimen has a length of 48 mm., and height 22 mm.

This species is distinguished from M, occidentalis by its lesser gibbosity; the convexity of the body is along the ventral side instead of the median line; and by the presence of undulating, filamentous radii.

Formation and locality. In the Yellow sandstones at Burlington, Iowa.

GOSSELETTIA, BARROIS.

Gosselettia triquetra.

PLATE XXXI, FIGS 9-17; AND PLATE LXXXVII, FIG. 12.

Pterinea triqueter, Conrad. Geolog. Surv. N. Y.: Ann. Rept., p. 116, 1838.

Mytilarea triqueter (Conrad), Hall. Prelim. Notice Lam. Shells, etc., p. 22, 1869.

Gosselettia triquetra (Conrad), Hall. Pal. N. Y., vol. v. pt. 1 Plates and Explanations: Pl. 31, figs. 9-17. Jan., 1883.

SHELL of medium to large size; body triangular, oblique; in young shells the height and length are nearly equal, in older shells becoming more elongate; anterior margin truncate, flattened on the ventral side; posterior margin broadly rounded.

Valves equal, very convex, sub-angularly gibbous along the ventral side. The convexity or breadth of the closed valves is about equal to the height of the shell. Ventral side vertical. Dorsal side sloping very abruptly in young individuals, and less abruptly in older shells.

Hinge-line straight, nearly or quite equalling the height of the shell. Beaks anterior, strong, elevated and incurved.

Test thick, marked by fine concentric lines of growth which are crowded and much elevated on the anterior side. In older specimens the strice become irregular and lamellose toward the basal margin.

Ligamental area comparatively wide and very finely striated longitudinally. Cardinal teeth three, strong and somewhat diverging. Lateral teeth elongate and extending nearly to the posterior extremity of the hinge-line. The anterior muscular scar is sub-circular, deep, situated near the inner border of the cardinal plate and truncating the anterior cardinal tooth.

A medium-sized specimen has a length of 58 mm., height 43 mm. breadth 41 mm. A larger individual has a length of 80 mm. and height 55 mm.

The older shells present some similarity to M. (Plethomytilus) oviformis, but the ventral angular slope is characteristic. In young specimens the triangular and extremely gibbous form distinguish it from all other species here described.

It is referred to the genus Gosselettia of Barrois, from the Devonian of Spain, on account of its similarity of external form and the strong cardinal teeth; otherwise it has all the characters of Mytilarca.

Formation and localities. In the shales of the Hamilton group, Fultonham, Schoharie county, and Onondaga county, N. Y.

Gosselettia retusa.

PLATE XXXIII, FIGS. 1, 2.

Gosselettia retusa, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 30, figs. 1, 2. Jan., 1883.

Shell of medium size; body very oblique, rhomboid-ovate, sub-arcuate; length one-third greater than the height; ventral margin nearly straight for two-thirds of the length, inflated at the byssal opening and concave below, thence abruptly curving into the broad basal and dorsal margin.

Valves equal, regularly convex in the posterior part and gibbous in the umbonal region; the point of greatest convexity is above the middle. The ventral umbonal slope is sub-angular. Ventral side flat.

Hinge-line short. Beaks acute, prominent, directed a little forward and incurved.

Test of moderate thickness, marked by lamellose concentric lines of growth which at irregular distances are crowded into fascicles.

Ligamental area and interior unknown.

The specimen described has a length of 49 mm., height 32 mm., breadth 30 mm.

This species differs from G. triquetra in its proportionally longer form, which is less expanded posteriorly; hinge-line shorter and less oblique to the body of the shell; and the ventral umbonal slope is less angular along the length.

Formation and locality. In the Hamilton group, Eighteen mile creek, Erie county, N. Y.

MODIOLA, LAMARCK,

SUB-GENUS MYTILOPS, HALL.

MODIOLA (MYTILOPS) PRÆCEDENS.

PLATE XXXIII, FIGS. 9-18.

Modiola præcedens, Hall. Prelim. Notice of the Lam. Shells, etc., pt. 2, p. 1. 1869.

Mytilops (Modiola) præcedens, Hall. Pal. N. Y., vol. v, pt. 1. Plates and Explanations: Pl. 33, figs. 9-18.

Jan., 1883.

Shell of medium size; body elongate, semi-elleptical, broadly and obtusely sub-triangular; length a little more than twice the height; byssal margin slightly sinuate; anterior end compressed, abruptly rounded, nearly straight or gently curving along the ventral side, acutely recurved at the posterior extremity, thence broadly rounded to the extremity of the hinge.

Valves equal, convex below, becoming gibbous and angular anteriorly. The line of greatest convexity extends from the beak to the post-ventral extremity, slightly arcuate.

Hinge-line slightly arcuate, sub-alate; length nearly half the length of the valve. Beaks small, sub-terminal, slightly incurved.

Test marked by fine, equal, concentric striæ, and by fine, wrinkled radii, which diverge along the median line and curve toward the opposite margins.

Ligamental area with one or two longitudinal grooves.

Interior unknown.

A small specimen has a length of 28 mm., and height 12 mm. A mediumsized specimen has a length of 36 mm., and height 17 mm.

Formation and localities. In a conglomerate of the Chemung group, Portville, Alleghany county, N. Y., and south-east of Smethport, Pa.

Modiola (Mythops) metella.

PLATE XXXIII, FIGS 23, 24; AND PLATE LAXXVII, FIG. 9.

Modiola metella, HAT) — Prelim. Notice Lam. Shells, etc., at. 2, p. 1.—1869.

Mytilops (Maliola) metella, HATE.—Pal. N. Y., vol. v. pt. 1.—Plates and Explanations: Pl. 33, figs. 23, 24

Jan., 1883.

SHELL large; body narrow elliptical, sub-arcuate, obliquely truncate on the anterior dorsal side; length more than twice the height; ventral margin gently curving, nearly straight for three-fourths of the length, thence abruptly rounded at the posterior extremity; dorsal margin very gently curving to the extremity of the hinge-line.

Valves equal, depressed-convex at the posterior end, becoming gradually more convex to a point anterior to the middle of the length, and gibbous in the umbonal region.

Hinge-line oblique, about equal to the height of the valve. Beaks small, appressed.

Test thin, marked by concentric striæ.

Ligamental area marked by two slender grooves. Other interior characters unknown.

A specimen has a length of 57 mm., height 25 mm., and hinge-line 24 mm.

This species differs from *M. præcedens* in its larger form, which is less expanded posteriorly, less angular and gibbous along the umbonal slope, and without radii on the surface so far as can be determined in the specimens.

Formation and localities. In a conglomerate of the Cheming group, at Panama, and in a boulder of similar rock on the road from Ellington to Cherry creek, Chautauqua county, N. Y., and at Warren, Pa.

Plates 11 and 13 Missing.

Fig. 6. A left valve, having the wing unusually large and extremely extended.

Chemung group. Mansfield, Pa.

Fig. 8. An enlargement of surface where the intermediate radii are nearly equal.

Fig. 9. An enlargement of surface showing the alternating small radii, and strong, concentric lamellose strice.

Hamilton group. Skaneateles lake, N. Y.

Fig. 10. An enlargement of a specimen preserved in calcareous shales, showing strong lamellæ and very nnequal radii.

Hamilton group. Hamburg, Erie Co., N. Y.

The weathering of specimens like the one represented in Fig. 10 often obliterates the finer surface ornamentation, and leaves the larger rays with transverse ridges marking the place of the stronger lamella, giving them a nodose character. A specimen in this condition was described by Mr. Courad as Avicula tuberculata, with distant tuberculated ribs and intermediate striat. Ann. Rept. Geolog. Surv. N. Y., p. 117, 1838. This name should have been cited in the synonomy of Avicula flabella, page 93 of this volume.

PTERINEA PINGUIS.

Hamilton group. Prait's Falls, Onondaga Co., N. Y.

Allocardium alternatum, gen. et sp. nov.

Fig. 15. A view of the specimen enlarged to two diameters. The relations of this shell are not apparent. It has the aspect of a bivalve shell in the characters of the rays and the cardinal aurientation, and somewhat resembles Hippages and Trigoniuma. With the present material it cannot be satisfactorily arranged with any known genus of molluses.

Hamilton group. Cayuga lake, N. Y.

Figs. 5. 6. The right and profile views of a small specimen showing the form and convexity of the shell. Hamilton group. Prait's falls, Onondaga Co., N. Y.

Fig. 7. An outline of a large right valve.

Hamilton group. Schoharie Co., N. Y.

Fig. 8. A left valve preserving very marked surface characters.

Hamilton group. Delphi, N. Y.

Fig. 9, A right valve showing the marked radii on the umbonal region and their gradual obsolescence toward the margin of the valve. The hinge preserves the striated ligamental area, the oblique lateral teeth and three obscure cardinal folds anterior to the beak.

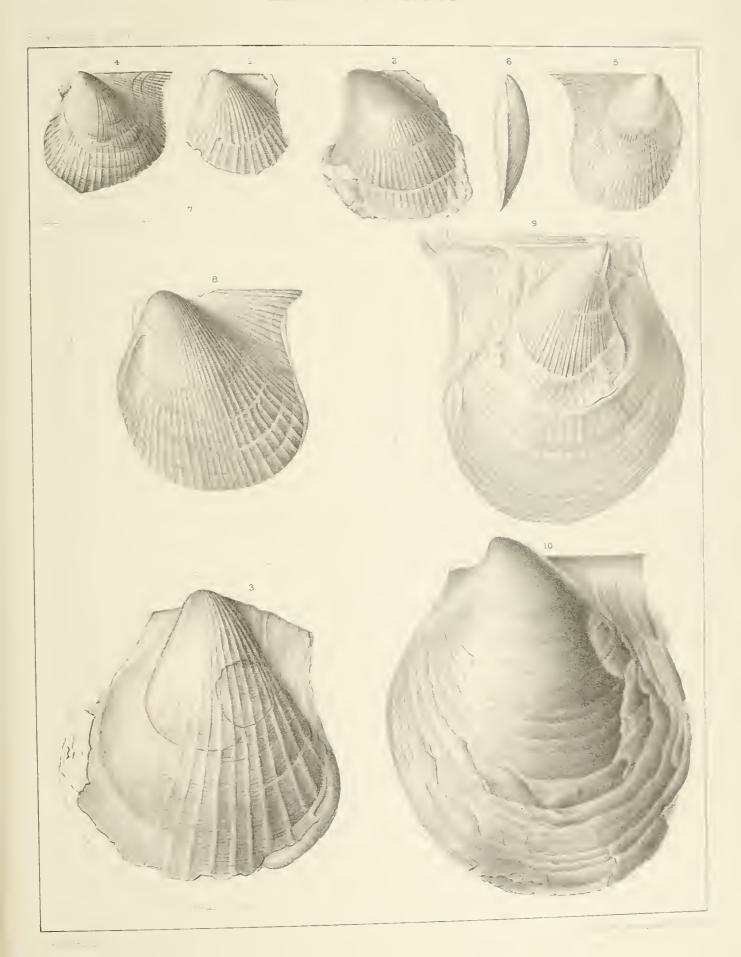

Hamilton group. Pratt's falls, Onondaga Co., N. Y.

LIMOPTERA OBSOLETA.

Page 249.

See Plates 26 and 29.

Fig. 10. A large left valve, showing the form and surface characters and a portion of the ligamental area. Hamilton group. Pratt's falls, Onondaga Co., N. Y.
